staining with acid stains such as acid fuchsin. The parasites are found only in the growing edge of the tumour and are absent from the centre; they are said to multiply by fission and segmentation, and perhaps, also, by budding. He found them in 1130 out of 1278 cases of carcinoma. Gaylord accepts Plimmer's bodies as parasites and also includes other forms such as Russell's fuchsin bodies. He relies chiefly on unstained specimens, but in an investigation of numerous specimens by Plimmer's methods he found them in every case of carcinoma and sarcoma that he examined and also in specimens of myxoma, adeno-fibroma, colloid goitre, and syphilitic lymphatic glands. According to him the parasites in the fresh state closely resemble fat globules from which, however, they can be distinguished by the fact that they are insoluble in ether and that they do not react like fat to osmic acid. He further states that the parasites can be detected in the blood of all cases of carcinoma and sarcoma in which cachexia is well marked. In opposition to Plimmer he says that the fluid obtained from the centre of carcinomata which have undergone degeneration consists practically of a pure culture or the organism.

As regards the cultivation of these parasites Plimmer was able from one case of carcinoma of the breast to isolate an organism which he identified as a blastomyces, and he was able by inoculating guinea-pigs to produce growths of endothelial origin in which he could recognise the organisms. Gaylord, on the other hand, working with a pure culture of Plimmer's yeast, was unable to reproduce in inoculated guinea-pigs bodies having a similar appearance to those met with in carcinoma. The results of inoculation were of a granulomatous nature. He was unable to obtain a culture of blastomyces from carcinomata except in one case, although he used as many as 64 different kinds of culture medium. Gaylord, by inoculating guinea-pigs with ascitic fluid derived from a case of carcinoma of the peritoneum, claims to have been able to produce nodules in the lungs which had some resemblance to carcinoma, but, judging from his illustrations, these nodules bear a close resemblance to the lymphoid nodules which are normally present in a guinea-pig's lung. His researches are being continued and we are promised a further communication on the subject.

We thus see that these two observers, both ardent advocates of the parasitic theory, differ from each other on some important points. Now it will be said, If these bodies are not parasites what are they? The answer to this question involves a consideration of the different inclusions which may be met with in carcinoma. Firstly, the cells of carcinomata are prone to degenerations of different kinds such as fatty, hyaline, colloid, and mucoid changes. According to the two observers, the parasites can readily be distinguished from the appearances due to these changes. The case, however, on which Gaylord made most of his observations was one of colloid carcinoma. Many pathologists, also, regard Russell's fuchsin bodies as resulting from hyaline degeneration. In the next place we meet with leucocytes and, occasionally, red corpuscles included in carcinoma cells. Of these, the red corpuscles would give rise to the greatest difficulty, but with reasonable care they should be readily distinguished. Then there are various appearances dependent on the rapid and irregular division of the cells, and it is here that the greatest difficulty would present itself. I have frequently seen a particle of chromatin which has become detached from the nucleus surrounded by a layer of protoplasm lying in the protoplasm of the epithelial cell, the whole forming a body exactly resembling one of Plimmer's bodies except that the nucleus stained with basic dyes. It is difficult to suppose that bodies so exactly similar should be of such entirely different characters, and I think it justifiable to suppose that those bodies in which the nucleus takes the acid stain may be of the same nature as those in which the nucleus stains with the basic dye, the nucleus having, perhaps, undergone some change which alters its staining properties. Gaylord states that he has succeeded in staining the nuclei of Plimmer's bodies with hæmatoxylin.

The various stages of endogenous formation may account for some of the structures supposed to be parasites. Sections through a daughter cell inclosed within a mother cell which do not pass through the nucleus of the daughter cell give rise to the appearance of a non-nucleated body lying in the epithelial cell such as is shown in one of Gaylord's illustrations. Again, nucleoli, especially plasmosomes, frequently escape from the nucleus into the protoplasm and give rise to bodies closely resembling the so-called parasites. Lastly, there are the centrosphere and its contained centrosome. Borrel,[18] who is in favour of the parasitic theory, has shown that alterations in the attraction sphere may give rise to exactly the same appearances as those described as parasites, and I think that no one who has seen the illustrations of his paper can have any doubt that the appearances which he ascribes to variations of the attraction sphere are the same as those which others ascribe to the parasites. In the spermatocytes of the testis of the guinea-pig there are bodies of archoplasmic origin which are sometimes called "paranuclei." These bodies are round and may contain one or more centrosomes; they stain with acid dyes and sometimes show a central spot which takes the stain more deeply than the periphery. They vary in size, some of them being almost as large as the nucleus. Like Plimmer's bodies, they are not found in cells which are undergoing mitosis. I am certain that if these bodies were seen in the cells of a carcinoma they would be at once branded as parasites. The appearances described by Plimmer as being characteristic of the parasites could all be explained on the assumption that they are of archoplasmic origin. Therefore, before these bodies are accepted as parasites the possibility of their being derived from pre-existing cell-structures must be fully considered.

From the foregoing remarks it will be seen that the grounds on which the parasitic theory is based are by no means satisfactory. I must next consider various objections to the theory. In the first place, as I have pointed out elsewhere,[19] we know of no disease characterised by definite anatomical lesions which is at the same time characterised by a definite extrinsic causal factor; neither do we know of any disease characterised by a definite extrinsic factor which is at the same time characterised by definite lesions. Therefore, since tumours are characterised by their anatomical structure, we should not expect them to be due to definite extrinsic causal agents. In the next place, we know of no parasites which are capable of producing primarily a proliferation of cells. Adami[20] is somewhat inconsistent on this point, for he says in one place that proliferation is an intrinsic property of the cell and is only influenced indirectly by external conditions and in another place he states that an irritant which, when concentrated, produces destruction, when diluted produces proliferation. In the case of all known parasites the first effect is injury or destruction, any proliferation which subsequently takes place being compensatory in nature to replace the cells which have been destroyed. I am not convinced that the proliferation of epithelial cells in coccidiosis is primary—that is, that the parasite directly causes proliferation. Even if a parasite were capable of causing a primary proliferation it would not explain the occurrence of a carcinoma since the essential lesion of carcinoma is not proliferation but is penetration of the epithelial cells into the connective tissue. In the next place, the reaction of the organism against all known parasites, animal and vegetable, is of a defensive nature and characterised by the phenomena of inflammation. The parasite first gives rise to injury or destruction of the tissues: this is followed by exudation of leucocytes which remove the damaged tissue and, if possible, the parasite, and this again by proliferation of the surrounding tissue which repairs the injury. A tuberculous nodule, for instance, is formed by centripetal proliferation of the surrounding tissue—that is, by proliferation taking place towards the irritant. It is far otherwise in carcinoma; here we have proliferation taking place in a centrifugal direction away from the supposed parasite and, instead of a defensive reaction, there is produced an ever-increasing amount of epithelial tissue in which the parasite can grow and multiply. In fact, the organism would seem to welcome the parasite instead of repelling it. This is so opposed to the accepted laws of parasitism that one may be excused for doubting its possibility. Some have supposed that the parasite acts on the cell in somewhat the same way as a sperm cell acts on a germ cell and thus induces proliferation. This seems to me a very far-fetched and unwarrantable supposition and is negatived by the fact that, as regards the parasites that have been described, the parasite-containing cell does not undergo division. To make sure of this fact, which was mentioned by Ruffer and Plimmer,[21] I recently wrote to Mr. Plimmer and he tells me that the cells several years have elapsed less than is that which exists on the opposite side. If the permanent teeth are lost in young life the alveoli waste and the bones along which force is distributed either as pressure or strain become progressively thinner. The rough, prominent surfaces to which the tendinous insertions of muscles are normally attached do not exist. This is seen most conspicuously in the case of the angle of the lower jaw which no longer presents the vertical ridges on its outer surface or the eversion of its margin characteristic of the normal vigorous state, but is rounded and smooth, a considerably larger angle being included between the posterior margin of the ramus and the lower border of its body. Precisely similar changes take place in the jaw of the edentulous old subject. The lower jaw is moulded upon the upper and anything that interferes with the free movement of these bones on one another impairs to a corresponding extent the development of the former.

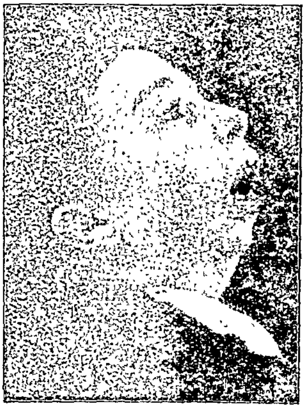
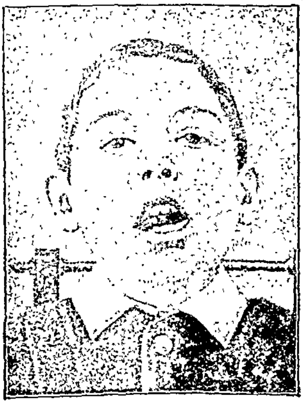
FIG. 1.



Showing the condition of a girl, aged 12 years, operated upon in 1893. The joint was destroyed when she was 18 months old, and at the operation all trace of it had disappeared completely.

FIG. 2.

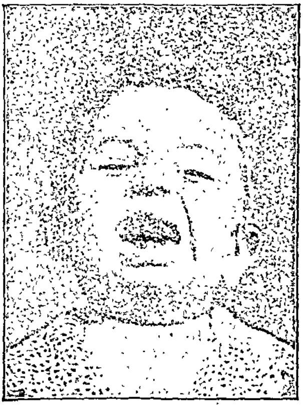


Representing the result of this operation on a boy, aged nine years, in 1892. The jaw was fused to the temporal bone, no evidence of the original joint being visible.

Figs. 1, 2, 3, 4, and 5 represent cases of ankylosis of the temporo-maxillary articulation which have been successfully operated upon, the ankylosed joint having been freely excised. They are introduced here as illustrating very well the fact that in them the degree of imperfection of the lower jaw varies directly with the duration of the ankylosis and inversely with the age of the child at the onset of the destruction of the joint. In these cases this factor alone—namely, the movements of the jaws and teeth on one another—was in abeyance, since the necessarily very efficient naso-pharyngeal respiration due to the complete apposition of the jaws had developed the naso-pharynx and the surrounding bones as completely as possible in a manner which will now be considered.

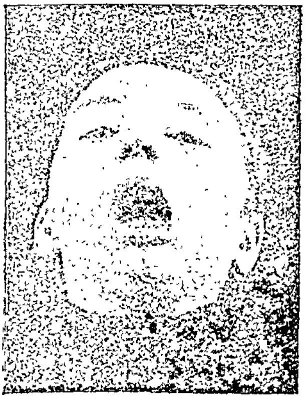
I need hardly repeat here that the eruption of all the teeth is necessary to the perfect development of the jaws. The pressure exerted by the tongue is an important factor in determining the form of the lower jaw. This is illustrated very well by the disproportionate size of the jaw, which is presented when the tongue is abnormally large, often resulting in an "underhung bite" or in "open bite," conditions very familiar to the dental surgeon. (See Figs. 6, 7, and 8.) I intend to discuss in detail in a subsequent communication the causation and treatment of these conditions.

FIG. 3.



A boy, aged four years, who was operated upon in 1894. The joint had been disorganised three years before.

FIG. 4.



A girl, aged 10 years, who was operated upon in 1896. The joint was destroyed when the child was seven years old.

I will pass on to study the mechanical influence which the passage of air through the naso-pharynx exerts upon its development and upon that of all the bones of the face, and showed sections of the tongue at different ages in confirmation of Thiersch's observations. These showed that the subepithelial connective tissue, which in the young is relatively abundant, continually decreases with the increase of age, while the overlying epithelium continues active, so that in old age there is a tendency for the epithelium to send down processes into the subjacent tissues.

We come now to the consideration of Ribbert's[24] theory. This author holds that the tissues in the normal condition are prevented from over-stepping their natural bounds by the action of the "tissue tension" of the part; if this tissue tension is diminished proliferation is set free and a tumour results. This tissue tension represents the sum of the physiological forces acting on the part and is equivalent to the physiological resistance of Cohnheim. According to Ribbert a tumour arises from a collection of cells or a piece of tissue which has become separated from its organic connexion with the surrounding parts and, in consequence, is not subject to the restraining action of the influence of the surrounding tissues; the rudiment is therefore free to proliferate and this proliferation results in the formation of a tumour. The separation of the rudiment may be effected by three means: (1) it may be separated by irregularities in the course of development; (2) it may be the result of trauma; and (3) it may be caused by inflammatory changes in the surrounding tissues. For instance, he explains the origin of carcinoma of the skin as follows. The earliest change is of an inflammatory nature, resulting in a new formation of connective tissue between the epithelium and the cutis vera; this new-formed tissue grows into the superjacent epithelium and isolates either single cells or groups of cells; these cells, being freed from their organic connexion with the rest of the epithelium, are released from the tissue tension of the part and therefore undergo proliferation, penetrating into the subjacent connective tissue and thus giving rise to a carcinoma. The new-formed tissue may be abundant or minimal in amount, but it is never absent. This theory of the causation of tumours is undoubtedly the most satisfactory one that we have yet considered and it possesses the merit of endeavouring to find a cause which shall satisfy the requirements of logic. It is available for the explanation of all tumours and of other conditions such as hypertrophy. I do not agree with Ribbert in assigning so great a part to the connective tissue in tumour causation. The difficulty of deciding this point is great because it is seldom that one examines a carcinoma in a sufficiently early stage, and it is impossible in many cases to say whether the changes observed in any particular specimen would have given rise to a carcinoma if it had been allowed to continue growing.

A theory which is closely allied to that of Ribbert is that which ascribes the origin of a tumour to the loss of nervous control over the cells of which it is composed. The tumour, not being under the control of the central nervous system, grows in an irregular and purposeless manner. This theory was supported by Marshall[25] in his Morton Lecture. The difference between this theory and that of Ribbert lies in the fact that, while Ribbert ascribes the origin of a tumour to the separation of its rudiment from the organic connexion with the surrounding parts, this theory ascribes it to the loss of nervous control. There is no proof that this loss of nervous control can give rise to tumour formation, but, on the contrary, there is ample evidence that it does not necessarily do so, as, for example, in skin-grafting. Beatson[26] suggests that carcinoma of the breast is due, in some way or other, to the influence of the ovaries. There is no evidence in favour of this idea except the fact that certain cases of carcinoma of the breast improve when the ovaries are removed. This fact, however, is not sufficient to form a groundwork of a theory of the origin of carcinoma, since the removal of the ovaries causes profound alterations in the metabolism of the body at large.

### ADAMI'S THEORY.

Recently Professor Adami[27] of Montreal delivered an address before the Yale University Medical Alumni Association in which he made known his views on the causation of cancerous and other new growths. It is difficult to give in a few words a *résumé* of this most interesting address and I must refer you for the details to the original. Professor Adami agrees, to a certain extent, with Ribbert that the initiation of a tumour is due to the alteration of the tissue tension, but he also admits the action of prolonged stimulation if at the same time the cells are in some way or other prevented from performing their specific function. Proliferation once started will continue as long as the primary modification of physical relationships or the primary stimulus continues to act, if there is adequate nutriment, and if the tensions acting on the cells do not become excessive. The longer the cells are diverted from the performance of their special functions to proliferative activity the greater the tendency for them to acquire permanently the "habit of growth"—that is, the power of proliferation independent of extrinsic conditions, and we thus obtain the purposeless cell-growth characteristic of a tumour.

Now, although I agree with Professor Adami's views to a large extent, yet there are a few points in his reasoning which, to my mind, are not quite satisfactory. In the first place, he states that the controlling agency in the higher katabolic activities of the cell, both functional and proliferative, is the nucleus. In this statement he altogether ignores the centrosome which, as we have seen, plays the leading part in the division of the nucleus and the cell. In the next place, he states that proliferation and the active performance of specific function are to a large extent incompatible owing to the different structure of the nucleus under these two conditions, and he argues from this that proliferation can only take place when the cell is unable fully to utilise the assimilated material in the performance of its specific function. I think, however, that in most cases we are equally justified, if not far more justified, in saying that the cell does not perform its function because it is undergoing division. He does not give any reason for supposing that the cessation of function precedes division, and it certainly seems more natural to suppose that the reverse is really the case and that the cell ceases to functionate because it is dividing. It is also impossible in many cases to draw a sharp distinction between the performance of function and proliferation, since in some cases the two are identical. Another defect in this theory is the fact that it does not explain the penetration of the epithelial cells into the surrounding tissues which constitutes the essential lesion in carcinoma. Nowhere in his address does Professor Adami refer to this penetration, but he seems to regard proliferation as the characteristic feature of carcinoma. We may, however, have any amount of cell proliferation without carcinoma, and, indeed, until penetration is present, we cannot be certain that we are dealing with carcinoma at all. Nothing that merely explains the presence of proliferation without at the same time explaining penetration can be satisfactory in affording an explanation of carcinoma.

# ON CLEFT PALATE.

BY W. ARBUTHNOT LANE, M.B., M.S. LOND.,
F R.C.S. ENG.,
SURGEON TO GUY'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE subject of this paper is the conditions of imperfect development of the septum between the mouth and nasopharynx which are comprised under the term "cleft palate." I will attempt to place the treatment of this deformity on a scientific basis and to do so it will be necessary to consider in the first instance the factors that determine the form of the bones of the face.

The functions of the bones of the face are four in number: (1) to surround the passages by which air alone is transmitted to the lungs; (2) to sustain the strain exerted by the muscles of mastication and to transmit and diffuse the resistance offered by the crushed food in the forcible approximation of the jaws during its attrition by the teeth; (3) to surround and protect the eyes; and (4) to accommodate the tongue.

Experiments are made by nature on all sides showing the influence which the exercise of these several functions exerts upon the skeleton, all capable of accurate measurement and definition. If an eye be removed early in life the degree of development of the orbital space which contained it, and of the soft parts which surrounded it, is after

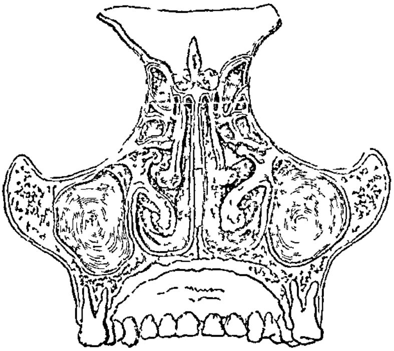
[25] THE LANCET, Nov. 23rd, 1889, p. 1045.

[26] Brit. Med. Jour., vol. i., 1899.

[27] Loc. cit.

It is well known how exceedingly common are such cases of imperfect development of the nasal cavity, of which Fig 10 is an excellent example It has often been observed that if such diseases of the nose, ear, larynx, and even lungs as are directly or indirectly consequent upon some imperfect development of the naso-pharynx could be excluded a not unimportant section of their consideration and treatment would have to be deleted from works on these subjects

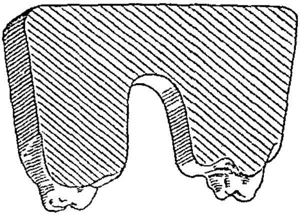
FIG 9



A vertical transverse section through the nasal cavities and adjacent structures

Indeed, if it were not for popular ignorance of the mode in which respiration should be performed and for the accidents associated with civilisation which often render it difficult to apply the knowledge even if possessed, the nose and throat surgeon would have practically no reason whatever to exist He is merely a product and an evidence of degeneration, and this fact he too often fails to appreciate It behoves us, therefore, to consider very carefully the factors which are responsible for these conditions of imperfect development, in order that by early and prompt treatment we may save our patients from innumerable complications, some of which may not at first sight seem to depend directly upon it I believe that they result solely from the fact that for some reason or other the mechanical factor that affects the development of the naso pharynx is in abeyance, and that in consequence this space does not enlarge as it should

FIG 10

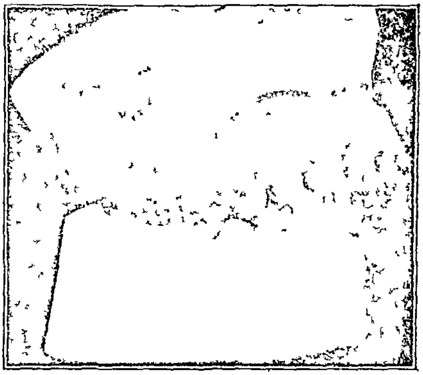


A transverse vertical section of the palate and alveolus, life size of an adult with an imperfectly developed naso pharynx The model was made by Mr Edgar Ashby

I have shown that the large majority of the conditions known to dental surgeons as "superior protrusion" result from deficient development of the naso pharynx (see Figs. 11 and 11A)

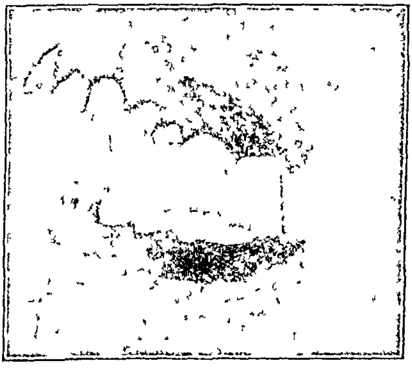
Of course, it is to be borne in mind that some children inherit a degree of development which is less than the normal An interesting and ready means is afforded, by the study of such imperfectly developed conditions, of determining how quickly an acquired deformity in the parent may arise in the offspring Personally, I believe that the transmission of this particular condition is very direct and rapid The absence of this developmental factor is brought about by an infection of the mucous membrane of the nose, of which the most common type is a cold in the head In the young subject the mucous membrane of the nasal cavities is peculiarly liable to inflammations, being usually the "area" of least resistance, and this inability to resist varies inversely with the respiratory capacity of the individual In those with a subnormal respiratory capacity the naso pharynx becomes the seat of recurring infections or of a chronic infection The inflammatory swelling of the mucous membrane and the presence of mucus interfere sufficiently with the entry of air during inspiration to make it necessary to breathe through the mouth Take some of those children who suffer from these attacks, and let them be observed carefully As they stand they assume the "symmetrical posture of rest," which is shown very well in Figs 12, 13, and 14 The chest is flattened in front, depressed, and the abdomen is thrown forward, the dorsal spine is flexed, the shoulders project forwards, and the lower angles of the scapulæ are prominent on the back of the chest To this condition the term "dorsal excurvation" is applied by the profession and that of "round shoulders" by the public If the child is standing at rest on one leg the trunk assumes the position which I have described as the "asymmetrical resting posture." This, from its habitual assumption, may have become fixed and later exaggerated By the profession this is described

FIG. 11.



A profile of a case of "superior protrusion resulting from imperfect development of the naso-pharynx

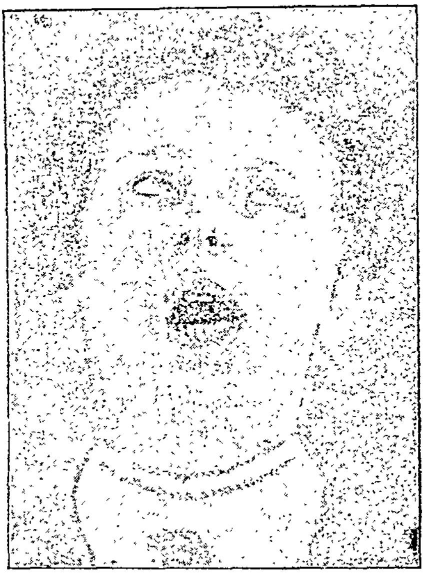
FIG 11A



A profile of a similar case with the jaws apart.

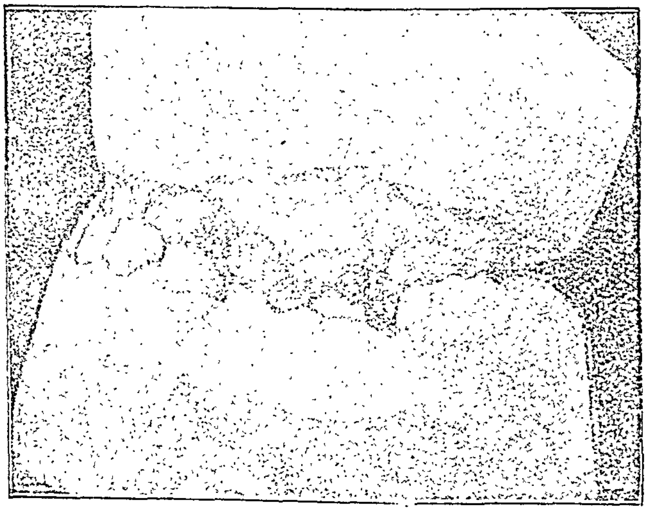
I think it will be quite clear that, under ordinary circumstances, its influence is paramount, being quite out of all proportion to that exerted by the factors to which I have already referred. The chief function of the naso-pharynx is to transmit air into the lungs in order that the sensitive surface of its mucous covering may become affected by substances contained in it. In other words, this part of the body is constructed essentially for the purpose of smell, and in the several groups of animals the degree of its development varies with the importance of the sense of smell to each. The upper portion of the nasal cavities is used for the ramifications of the olfactory nerve, and the current of air is distributed especially over this area by the act of sniffing. During the normal process of respiration the mouth is kept shut, the upper lip covering the upper incisor teeth entirely and projecting below them. The breathing air passes chiefly through the lower meatus, while there is hardly any current in the upper part of the space. It is therefore obvious that anything interfering sufficiently with the calibre of the lower part of the nasal cavities impairs their capacity for transmitting air to an extent to make it necessary to keep the mouth open while breathing. When this is done air enters so freely through the larger and more direct channel formed by the mouth that it ceases to pass through the nose either during inspiration or expiration; the most important function of the part is lost, and the forces which act upon it normally and develop it are in abeyance. Even after air has ceased to pass through the nose in inspiration it does so during the expiratory process of vocalisation, though in a diminishing degree. Therefore the so-called nasal intonation does not develop as early as one would imagine in association with much loss of nasal inspiration. It is seen at once from an examination of Fig. 9, which represents a vertical transverse section through the nasal cavities and surrounding structures in the normal subject, that the calibre of the lower part of the nasal cavities, or of their respiratory section, if I may so describe it, is enormously encroached upon by any ascent of the hard palate above the normal level, and that the air-transmitting capacity of the naso-pharynx varies inversely as the height of the palate; also that the calibre of the entire nasal space is very much affected by the slightest variation in the interval between the septum and the structures forming the outer wall of the space, such as is necessarily associated with any cramping of the alveolar arch laterally.

FIG. 5.



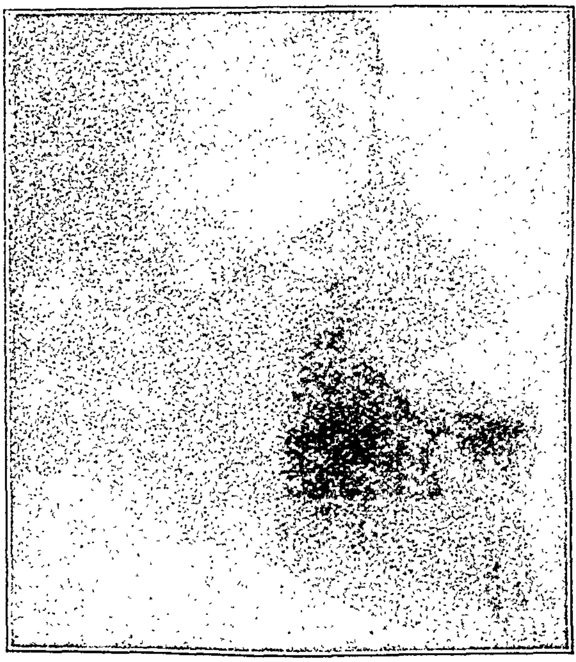
An adult whose joint had been disorganised in infancy. The operation was performed in November, 1895, and the illustration represents the condition of the patient in April, 1896. In 1902 her joint was working excellently.

FIG. 6.



A specimen of "underhung bite."

FIG. 7.



A radiograph of a case of "open bite."

FIG. 8.

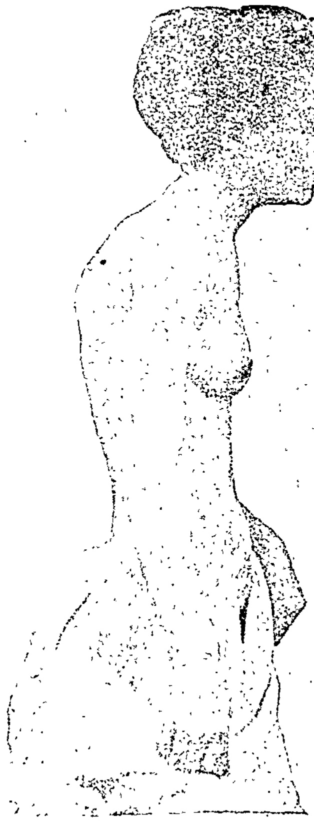
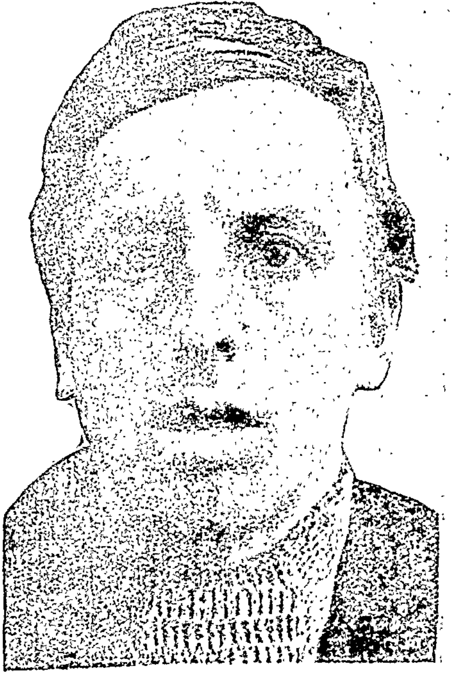
and naso-pharynx. It is kept open, and more or less of the upper incisor teeth are seen. In some cases even the gum may be exposed. The nose immediately above the lower lateral cartilages is compressed laterally, and little or no movement can be observed in the narrow slit-like anterior nares during respiration. The nose is frequently tip-tilted, so that its under-surface looks somewhat forward. On either side of the nose the face below the orbit is hollowed, the normal rounded prominence of the part being wanting. Owing to the interference with the development of the septum, consequent on the imperfect descent of the palate, deflections of this structure and the formation of "spurs" upon it are frequently very marked features, and with their immediate neighbour, the inferior turbinate bone, may call for surgical treatment in some instances with the greatest possible benefit to those adult patients whose nasal breathing space is so rendered very much less than normal and correspondingly insufficient. The width of the face forming the cheeks is less than normal, the malars being flattened and the whole face being wedge-shaped. These changes are particularly noticeable in Fig. 15. Looking into the mouth you notice that the alveolar arch of the upper jaw is compressed laterally and that the palate is very high along its central part. Indeed, the height of the palate bears a direct proportion to the changes just mentioned in the nose and face, or, in other words, the development of the nasal cavities varies inversely with the height of the palate and with the breadth of the alveolar arch. The lateral diminution in the breadth of the alveolar arch of the upper jaw results in its elongation in an antero-posterior direction, in which case the upper incisors project forwards considerably beyond the lower, constituting the "superior protrusion" of dentistry. Or this forward protrusion may be obviated by a corresponding amount of irregularity of the teeth. If a large number of models of cases of superior protrusion be examined it will be found that with very few exceptions the condition is consequent on imperfect development of the naso-pharynx (see Figs. 10 and 11). The width of the alveolar arch of the lower jaws bears a direct relation to that of the upper, upon which it is moulded in its development. The faucial tonsils are probably large, as is also the pharyngeal tonsil. There may be a variable amount of deafness owing to imperfect aeration of the middle-ear, to obstruction to the exit of mucus from it, or to interference with the function of the Eustachian tube. The deficiency in vitality consequent on, and proportionate to, the degree of imperfection of aeration of the blood in the lungs results in the child catching cold readily. The infection starts in the naso-pharynx and may extend to the larynx, trachea, and bronchial tubes. There is often a chronic snuffly cold in the head, with perhaps some irritation of the anterior nares and not infrequently of the upper lip also. The muscles of such children are usually soft and flaccid and their degree of intelligence is very variable. Sometimes they are considered dull and stupid, while others, on the contrary, are said to be very intelligent. This, I take it, varies with the state of the nutrition of the brain and with the variety of the demands made upon it. If the child uses up its limited brain power in muscular exertion its capacity to make intellectual effort is small, while if the same energy is employed intellectually under pressure that to spare for the muscles is correspondingly decreased. It also depends to some extent on their

FIG. 14.



Symmetrical posture of rest

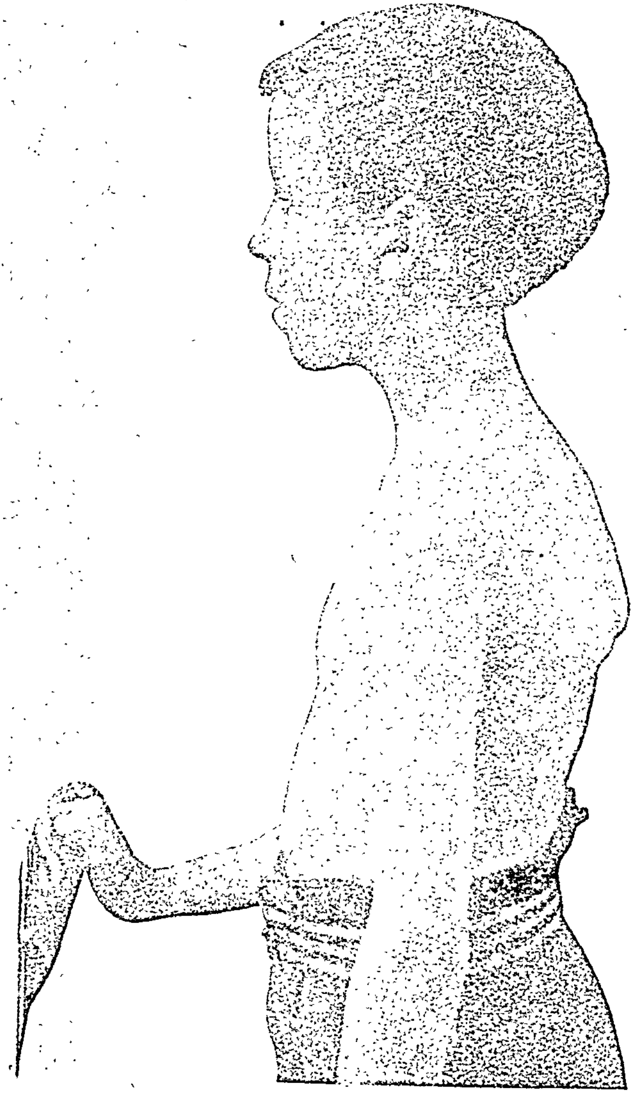
FIG. 15



Representing a case of imperfect development of the naso-pharynx.

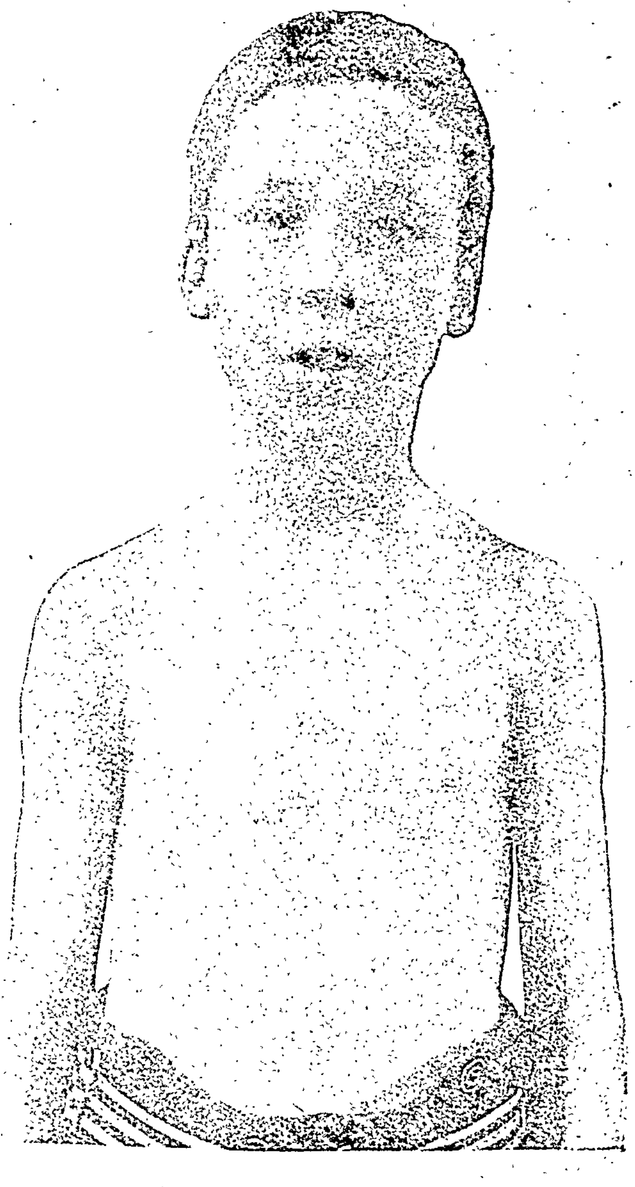
as "scoliosis" or "lateral curvature," while the public, being most struck with the prominence of the right scapula, regard it as "growing out of the shoulder." It may be fixed or exaggerated if the period during which it has been assumed is of sufficiently long duration. Respiration is superficial, rapid, and entirely diaphragmatic. A tape encircling the chest at the level of the nipple shows probably no variation whatever during ordinary inspiration and expiration. If the patient is told to breathe as deeply as possible the measurement of the chest is increased to a varying degree above that point, but it returns to it in expiration, the normal position being that of almost complete expiration. The skin of the chest is opaque and white, and is marked by large, conspicuous, dark-coloured veins in which the circulation appears stagnant. On looking at the back the skin is seen to be covered over a varying area by a fine down which extends beyond the middle line and becomes continuous above with the hair of the scalp. The margin of the hairy scalp is equally ill-defined in front, encroaching often to a considerable extent on the forehead and on the cheeks in front of the ears. Again, the feet are retained usually in a position of abduction, including between their inner margins a considerable angle. This position of the feet may after a time become fixed and later exaggerated. This I showed to be merely the habitual assumption by the foot of the "position of rest" or of abduction, but by the profession and the public it is spoken of as "flat foot." The condition of knock-knee, or a diminution of the normal external femoro-tibial angle, is not unfrequently seen in a slight degree, due to the habitual assumption of the resting erect posture, whether symmetrical or asymmetrical, but especially the latter. During the time the position is being assumed most of the superjacent weight falls outside the knee-joint, so that the outer part of the epiphysial line is exposed constantly to a much greater pressure than that sustained by the inner segment. In consequence, a correspondingly smaller amount of bone is formed by the outer part than by the inner, the femoro-tibial angle decreasing proportionately. This general law I formulated in the following words: "The several parts of a growing line form bone at a rate inversely proportionate to the pressure which they transmit." And one might add to this that these conditions are exaggerated in proportion as the nutrition of the osseous system is impaired, as, for instance, in rickets and the excessive growth which ensues in the skeleton in prolonged recumbency. The head is thrown forward (see Figs. 12 and 14) because of the flexion of the dorsal spine which is of necessity associated with expiration, flexion and extension of the spinal column being, as I explained, the most conspicuous of the thoracic respiratory processes, and produced chiefly by the action of the intercostal muscles, the internal being the most powerful but indirect extensors of the dorsal spine, and the external the most powerful flexors. They exert their action upon the vertebræ through the ribs. Those muscles are associated in their action with such portions of the internal and external abdominal oblique the fibres of which continue their directions. The mouth is small in proportion to the deficiency in the development of the jaws

FIG. 12.



Symmetrical posture of rest.

FIG. 13.



Symmetrical posture of rest.

corpuscles is undoubtedly altered. Thus I have found that defibrinated rabbits' blood, if kept for a day or two, showed hæmolysis after 19 hours at 13° C. in a solution which was isotonic for the same blood in a fresh condition. Stewart's results, recently published, furnish a corroborative instance. "There is," he states, "a noteworthy distinction between the perfectly fresh corpuscles and corpuscles which have stood some time in the length of the period of resistance to the entrance of $NH_4Cl$, which is much greater for fresh than for stale corpuscles." Other reasons for discarding the use of defibrinated blood are to be found in the chances of bacterial contamination, and the difficulty of obtaining fresh defibrinated blood when required. I accordingly use blood obtained fresh from an ear-vein. It was found, however, that if no precautions were observed to prevent clotting the control tubes containing isotonic salt solution showed at the end of 19 hours distinct hæmolysis. This autolysis may be attributed in great probability to the fibrin carrying down the proteolytic enzyme of the blood, which in some way influences the permeability of the stroma of the cells. To obviate this a solution was made up consisting of 0·1 per cent. sodium oxalate and 0·85 per cent. sodium chloride. The blood on escaping is at once thoroughly mixed with this solution. This procedure proved quite effectual in preventing autolysis of the red corpuscles. Microscopical examination of a hanging drop showed that, on the whole, the cells preserved their contour with comparatively little variation from the normal—slight crenation of the corpuscles proving that the fluid is, in fact, somewhat hypertonic. It is advisable that the osmotic pressure of the medium should be slightly greater rather than exactly equivalent to that of the corpuscles; the balance of osmotic pressure is then less easily disturbed by adventitious causes. It has been stated, as a matter of fact, that normal human plasma is hypertonic with respect to the red corpuscles. Another point which arises by implication from what has been already stated is the question of the time limit, which may be considered a fair one for the exposure of the blood to the hæmolytic agent. I believe that conclusions derived from experiments of a duration of over 19 or 20 hours are of uncertain value. Careful controls should be simultaneously carried out with isotonic salt solution.

So far as one has read of the methods of conducting these experiments, roughly quantitative tests, varying rather widely in the way they are carried out by different observers, appear to be used. It seems desirable that greater accuracy should be introduced into the procedure adopted, because if one wishes to investigate the comparative powers of two or more different fluids containing the same hæmolysin, or if variations in the permeability of different corpuscles be the subject of inquiry, the results are invalidated unless absolutely identical conditions have obtained during the experiments. For this reason it is necessary to add definite percentages of the hæmolytic fluid to the isotonic solution in which the corpuscles are suspended. In the same way equal amounts of blood, measured accurately in a calibrated pipette similar to those used in the various kinds of blood-estimation apparatus, should be added to each test-tube. These must be of equal diameter, in the lower part at least, so that the hæmoglobin diffused in the liquid may be estimated with greater accuracy. The spectroscope may be requisitioned in cases where a slight or doubtful hæmolysis has taken place. Complete sedimentation of the corpuscles by means of a rapidly-revolving centrifuge is important, because the hæmoglobin bands are given equally by the red cells and by the hæmoglobin after it has left the corpuscles. It is obvious, also, that the use of perfectly fresh blood in the manner described will ensure more trustworthy results for comparative purposes than if specimens of defibrinated blood of different ages be used. An advantage to be gained by instituting an accurate system of examination in hæmolytic tests is that a method conducted on these lines is easily adaptable for clinical application.

To summarise the steps briefly:—1. Use absolutely fresh unclotted blood. 2. Prepare in test-tubes of equal size known percentages of the hæmolysin in isotonic oxalate solution. 3. Add to each of the tubes exactly the same amount of blood and mix well. 4. Incubate tubes for the same length of time at 37° C. 5. Centrifugalise till all the corpuscles settle at the bottom of the tube, forming a sharp line of demarcation between the blood and the supernatant liquid. 6. In every experiment have control tubes containing isotonic salt solution alone. 7. In doubtful cases examine microscopically.

# PRIMARY SARCOMA OF THE VAGINA.

BY H. MACNAUGHTON-JONES, M.D., M.A.O. Q.U.I.,
F.R.C.S. IREL. AND EDIN.

A CASE of primary sarcoma of the vagina is of such comparatively rare occurrence that a special allusion to one which has recently come under my care justifies my giving it prominence through the columns of THE LANCET.

I am indebted to Dr. Otto Seitz, of Professor Winckel's Universitie Frauenklinik in Munich, for a recent synopsis of the literature of the subject, which may be of interest in a condensed form.[1] Of all the cancer cases occurring in the hospitals at Berlin and Vienna some 20 per cent. were of the nature of vaginal carcinoma, and of 8287 cases of cancer in Paris only 14 had primary vaginal carcinoma. It would appear that vaginal sarcoma is still more rare. The first case was published in 1872, and up to 1899 there had been 32 cases recorded. In medium-sized growths there is a quantity of cellular tissue with spindle-shaped cells and oval nuclei, epithelial and big round cells, the nuclei differing in size and staining. The pavement epithelium is absent, the blood-vessels are normal, and the lymphatics are richly developed. In larger growths, Dr. Seitz says, the endothelium of the lymphatic glands contains spindle-shaped cells, the lumen in some cases being nearly occluded. There is a general tendency to proliferation of the endothelium. There are spindle-shaped cells with horseshoe nuclei, giant cells, and others with vacuoles in the nuclei. No oblique muscle-fibres could be discovered. In a case recorded by Professor Klein the patient was aged 56 years, the growth grew from the posterior vaginal wall, and the starting-point was the para-vaginal connective tissue. The lymphatics were dilated and they contained blood. Gebhard has recorded a case of a girl, aged 14 years. Here there were alveolar spaces lined with endothelium and endothelial proliferation. The vaginal pavement epithelium was intact and the probable origin of the growth was the same as in the last instance. Again, in Amann's case there were spindle-shaped cells due to lymphatic endothelial proliferation. Franke's patient was an old woman. The new growth occurred in the posterior vaginal wall, in the nature of a hard infiltration, and the starting-point appeared to be in the vascular endothelium. The inguinal glands were normal. In 1898 Rubeska published a case of cure of the sarcoma, and Yung reported three cases in 1899. The first was in a patient aged 50 years. For some time there had been an irregular foul-smelling discharge. The tumour, which was of the size of the fist, grew from the right side of the vagina and was enucleated. The inguinal glands at the time were normal. There was a return of the growth 11 months after, though the glands were still normal. There was a second operation, with profuse hæmorrhage. Pathologically the growth contained both spindle-shaped and giant cells in large numbers. Vaginal pavement epithelium was absent. In the second patient, aged 52 years, there had been purulent discharge from an ulcerated surface in the right vaginal wall where the growth was situated. The glands were normal. There was a rapid return of the tumour and another operation at the end of two months, and, again, three months later the tumour, which was found to be of the size of a bean, in the left vaginal wall was excised. The patient was seen for the fourth time three months after the last operation. The tumour then occupied the whole of the right wall of the vagina. It was immoveable, with an ulcerated surface. The glands were normal and the patient was still at work. The pathological features of the tumour were those of a round-celled sarcoma. In the third case, that of a woman aged 30 years, the tumour was of the size of a small apple and was pedunculated; it appears to have grown rather from the margin of the external surface of the os uteri than from the vagina. Microscopically it proved to be a small and round-celled sarcoma.

As to the seat of vaginal sarcoma in adults, it would appear that out of 25 cases it grew from the anterior wall in 15 and from the posterior in 10. The disease is more common under the age of 50 years. Of 27 patients, greater association with people older than themselves owing to their dislike to engage in active games.

---

[1] Uber primäres Scheidensarkom Erwachsener, Gynakologie, No. 107, by Otto Seitz of München.

Now, it is clear that every child who is suffering in this manner does not exhibit all these evidences of a purely mechanical relationship to its surroundings described here, but they all show that the process of aeration of the blood is carried out very imperfectly, and in consequence the blood is not oxygenated in a satisfactory manner. Respiration is diaphragmatic, while thoracic respiration is completely neglected. Diaphragmatic respiration is a more perfect reflex than thoracic respiration and requires much less effort for its performance. For this reason it is, as is apparent to all, employed alone, to the practical exclusion of thoracic breathing by feeble subjects, both young and old. Because of a deficient supply of oxygen the child therefore has not enough energy to carry on the work of the muscles, brain, and other tissues of the body, or to protect itself from the power that organisms have of obtaining a foothold on tissues whose vitality is lowered by injury of some sort. In the young subject the mucous membrane of the nasal cavity is that which, from local depreciation by cold, becomes invaded most readily by organisms which, having secured themselves there, manifest their occupation by symptoms which are popularly comprised under the term "cold in the head." As the result of their presence the nasal cavity, with those cavities which communicate with it, becomes more or less completely blocked by the swelling of a very vascular mucous membrane and by the inflammatory secretion poured out from its surface. The lymphatic tissues in the vicinity become secondarily inflamed. These exist as irregular masses in the wall of the upper part of the pharynx and are described as the "pharyngeal tonsil." Whenever they have become more or less chronically enlarged, in consequence of the infective process in the mucous membrane with which they are necessarily associated, they are dignified by the dread and unmeaning name of "adenoids." Surgeons under the influence of the suggestion of Wilhelm Meyer have considered that the secondary infection of the so-called pharyngeal tonsil is the primary cause of the obstruction of the naso-pharynx, and they have hoped to cure their patients by cutting away a varying proportion of this substance. It is quite apparent that the removal of this lymphatic tissue cannot alone restore to the naso-pharynx the mechanical factor which is the active agent in its development, since it does not increase the respiratory power of the individual and consequently does not improve the resistance of the naso-pharynx to infection. If, however, this operation is associated with such measures as bring about an improvement in the respiratory capacity and forcible ventilation of the naso-pharynx, such a procedure may frequently be of considerable service. What a misfortune it was when this name of adenoids was applied to this collection of inflamed lymphatic tissue subsequent generations will recognise with amazement; but for the time, at all events, it has served to popularise an operation which everyone who has a ring knife or even a long finger-nail believes himself capable of performing sufficiently skilfully. It is well known how this operation has been modified by time. At first a small piece was picked out by biting forceps, without an anæsthetic, this process being repeated at intervals as frequently as the patience and the income of the sufferers allowed. For some considerable time now the removal has been effected at a single sitting under an anæsthetic.

The faucial tonsil, whose lymphatics are closely associated with those of neighbouring parts and whose resisting capacity is depreciated equally with that of the naso-pharynx, not infrequently becomes inflamed in consequence of septic absorption, as may also the lymphatic glands in the neck which receive the lymph-supply from the masses above them. These enlarged cervical glands, the vitality of which is depreciated by this septic process, readily become colonised by tuberculous organisms which are supplied in abundance in food and air. If a vigorous child becomes affected by a cold in the head he never rests till he has cured himself by the forcible and free ventilation of the naso-pharynx by powerful inspiratory and expiratory efforts In other words, he blows his nose and snuffles vigorously till he has restored the inflamed mucous membrane to its normal condition. The feeble child does not do this, but is satisfied to obtain the small portion of oxygen which he requires by keeping the mouth open. The organisms continue to thrive under these circumstances which are most favourable to them, as opposed to the individual; and the conditions dependent on their presence continue to increase, depreciating still more the vitality of the sufferer.

# A NOTE ON THE METHODS OF CONDUCTING HÆMOLYTIC EXPERIMENTS.

BY G. F. PETRIE, M.B., CH.B. ABERD.,
RESEARCH STUDENT, BACTERIOLOGICAL DEPARTMENT, JENNER INSTITUTE
OF PREVENTIVE MEDICINE.

I HAVE had occasion recently during the course of work bearing upon the products of the bacillus pyocyaneus, carried out at the suggestion of Dr. Allan Macfadyen, to make a number of experiments relating to the hæmolysins elaborated in the course of its growth. These have been shown, first of all by Bulloch and Hunter, and somewhat later by Weingeroff, to exist in cultures filtered a variable time after the date of inoculation. So far as the scope of my work in this direction has extended, the conclusions arrived at coincide in the main with those of the above-mentioned authors. Thus the resistance of the pyocyanolysin to heat was found in my experiments to be very great. On the other hand, hæmolysis seemed to go on equally well at comparatively low temperatures—e.g., exposure at 13° F. for 19 hours without preliminary incubation at 37° C. as usually recommended. The fluid chiefly used was a Berkefeld filtrate of a culture derived from the laboratory stock culture grown between 20° and 25° C. for four months in the solution recommended by Emmerich and Low as a suitable medium for the growth of the bacillus pyocyaneus The medium before inoculation was tested on the blood selected for the experiments and was found to cause no hæmolysis. Ordinary peptone broth cultures were also employed, and it was observed that no hæmolysis took place until the cultures were incubated for at least a week at 37° C. (this refers, of course, to the filtered cultures).

In carrying out these experiments a considerable amount of evidence accumulated to shew that hæmolytic tests present a wide margin of possible fallacy in the conclusions arrived at from positive results. It must be remembered that hæmolysis is not a phenomenon dependent only on specific complex bodies found in cultures of various micro-organisms. On the contrary, it is, of course, well known that extremely simple agents, such as distilled water, solutions of certain simple salts, &c., easily bring it about, and that the reaction of the medium has an important influence. The complexity of the constituents entering into the composition of cultures after bacterial growth has gone on for some time makes it extremely difficult to appreciate the exact rôle played by each of them in a phenomenon of the nature of hæmolysis, and it is therefore important to complicate the reaction as little as possible. With a view to lessening the risks of misinterpreting positive results it seems preferable to avoid, as far as possible, the use of preservative reagents, especially in cases where a comparative estimate is required of the hæmolysis of several kinds of blood. It is significant that each of the constituents of Ehrlich's reagent—carbolic acid, glycerine, and distilled water—is capable of hæmolysing red corpuscles. I have found that in the proportion recommended—viz., 5 per cent. of the solution to be tested (in this experiment 5 per cent in isotonic solution)—50 per cent. of the resulting fluid added to an emulsion of blood in isotonic solution caused well-marked hæmolysis and 20 per cent. distinct hæmolysis of rabbits' red corpuscles. In cases in which the lysin is destroyed by heat—e g., the staphylolysin—a simple control test is provided, but it is otherwise with hæmolysins, such as the pyocyanolysin and typholysin, which seem to possess very great heat-resisting powers Then, again, apart from the composition of the medium in which the corpuscles are immersed, the condition of the cells themselves is a factor which must be taken into account in assessing the value of the results obtained in hæmolytic experiments Defibrinated blood, if kept even at a fairly low temperature, is liable to undergo autolysis, and short of this the permeability of the red then passed through a Berkefeld filter, and the filtrate was tested for hæmolysins. Varying quantities of the filtrates were placed in a series of test-tubes and each was made up to five cubic centimetres by the addition of salt solution (0·85 per cent.). To each tube one-twentieth of a cubic centimetre of defibrinated dog's blood was then added and the tubes were kept for two hours at 37° C., and subsequently for 12 hours in the cold room before examination. I may here state that neither human blood nor the blood of rabbits or guinea-pigs form suitable media for testing the hæmolytic properties of the typhoid bacillus. The most suitable blood is that of the dog and the same observation applies to the dysentery bacillus. Pane objects to E. and P. Levy's results on the ground that the red corpuscles of the dog part easily or spontaneously with their hæmoglobin. I cannot confirm this statement of Pane, for in all control tubes made with salt solution and dog's blood I could not detect any trace of hæmolysation.

In order to be as brief as possible, I have collected my results in the following table. The table gives only the results obtained by using 0·5 cubic centimetre doses of the filtered culture, this being as a rule the maximum amount which I used.

| — | Age of cultures in days. | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 3 | 5 | 7 | 10 | 12 | 14 | 15 | 16 | 18 | 20 | 25 | 30 |
| Typhoid bacillus... ... | – | – | – | $+^{-}_{-}$ | +– | ++ | ++ | + | +– | $+^{-}_{-}$ | – | – |
| Dysentery bacillus... ... | – | – | – | – | $+^{-}_{-}$ | ++ | ++ | +– | $+^{-}_{-}$ | $+^{-}_{-}$ | – | – |
| Colon bacillus I. | – | – | – | – | $+^{-}_{-}$ | $+^{-}_{-}$ | $+^{-}_{-}$ | – | – | – | – | – |
| Colon bacillus II ... ... .. | – | – | – | – | – | – | – | – | – | – | – | – |

++ equal complete; + equals almost complete; +– equal partial; $+^{-}_{-}$ equal slight: and – equals no hæmolysation.

As will be seen from the table, the typhoid bacillus is capable of forming a hæmolysin which produces a complete solution of the erythrocytes of the dog's blood. The maximum amount of the hæmolysin is found in cultures of about two weeks old. Filtrates from 14 days' cultures produced complete hæmolysation in much smaller amounts than 0·5 cubic centimetre; for example, 0·01 cubic centimetre proved sufficient.

The dysentery bacillus gave equally positive results and thus presented a new point of resemblance, in addition to the many others, to the typhoid bacillus.

The colon bacilli did not exhibit any marked hæmolytic properties, either as regards the erythrocytes of the dog or those of other animals. I have, however, only tested two races of the colon bacilli, and it is possible that other strains may possess hæmolytic properties.

As regards the typhoid bacillus, I have been successful in obtaining an anti-hæmolysin. For the purpose a rabbit was treated with a filtered typhoid culture which contained active hæmolysins. The serum of the rabbit developed anti-hæmolytic properties 10 days after the first injection of the typhoid culture. On the addition of 0·05 cubic centimetre of the serum of the treated rabbit to an amount of the typhoid hæmolysin capable of producing complete hæmolysis of one-twentieth of a cubic centimetre of dog's blood, the solution of the dog's erythrocytes was inhibited. The serum of a normal rabbit used as a control did not exhibit any anti-hæmolytic properties.

I am indebted to Dr. Allan Macfadyen for the help which he has afforded to me as well as for the performance of the necessary inoculations.

---

EXETER GUARDIANS AND VACCINATION.—At the meeting of the Exeter Court of Guardians held on Feb. 4th it was decided to thank a gentleman who had forwarded the fees for the vaccination of his children by the public vaccinator to the guardians. One guardian remarked that it was a sin for people who could pay for vaccination to be vaccinated by the public vaccinator. Another guardian said that there were two sides to the question, as vaccination was essential for the public safety and the public should not grumble at the expense.

# A CASE OF PERFORATED GASTRIC ULCER SIMULATING APPENDICITIS.

BY C. A. B. HORSFORD, M.B., CH.B. EDIN.,
RESIDENT MEDICAL OFFICER, ROYAL ALBERT HOSPITAL, DEVONPORT.

THE following case may be of interest to the readers of THE LANCET, not only because of its comparative rarity, but because it illustrates well the possible similarity between, and the frequent difficulties in the diagnosis of, the above-named conditions.

The patient, a married woman, aged 32 years, was admitted to the Royal Albert Hospital, Devonport, on the evening of Monday, Jan. 13th, 1902. On the previous Wednesday morning (Jan. 8th), before breakfast, she had an attack of acute pain in the abdomen, most marked in the right hypochondrium. Vomiting soon commenced and persisted at intervals throughout the day. The *conjunctivæ* were somewhat jaundiced, but the urine contained no biliary constituents. Tenderness was marked over the gall-bladder. The abdomen was generally flaccid and there was no distension. The temperature remained normal during the day and the patient showed no signs of collapse. For two years she had suffered from "attacks of indigestion" with occasional vomiting, but she had never had any hæmatemesis. On the 9th the temperature rose to 100° F., but after the constipation, which had been present for some days, had been relieved by repeated turpentine enemata her condition seemed to improve considerably. On the 11th, however, she had another attack of severe pain. Her right leg was drawn up and tenderness at McBurney's point and slight bulging in the right iliac fossa were marked. Vomiting of bile-stained fluid was frequent and on the evening of the 11th it had a marked stercoraceous odour. The temperature was then 100° and the pulse was 95. Nothing definite was revealed per vaginam. A diagnosis of appendicitis was made but no operative interference was considered necessary. On the 13th she was decidedly worse. The pain extended all over the lower half of the abdomen, and as she was rapidly losing strength she was sent to the hospital.

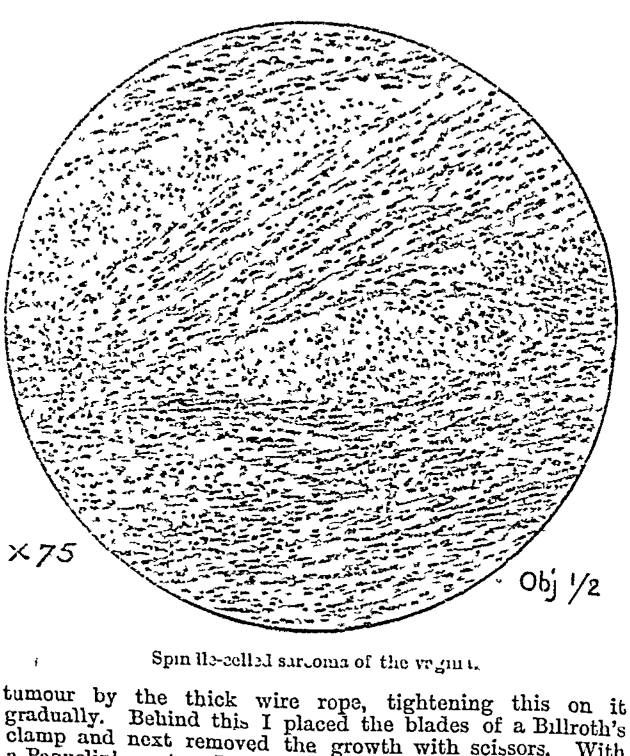
On admission the patient appeared to be in great pain and considerably exhausted from want of sleep. Her temperature was 99° and her pulse was 88 and of good quality. She had vomited that forenoon, but not since. The abdomen was not generally distended, but it bulged slightly in the hypogastrium and right iliac region. There was slight movement of the upper part with respiration; tenderness was acute in the lower half but only slightly so above, and on percussion a dull area was found in the right iliac fossa. Liver dulness was present. Per vaginam there was great bulging of the anterior vaginal wall, the uterus being pushed backwards and upwards. This was confirmed per rectum and there was obviously a large collection of fluid in the pelvis. It was decided to perform laparotomy on the next morning. The patient took small quantities of milk at frequent intervals without discomfort and after a hypodermic injection of one sixth of a grain of morphia she passed several hours in comparative ease. At 1 A.M. her condition appeared to be no worse, but at 4.30 A.M. she suddenly became collapsed. She was cold, sweat poured from her, her abdomen became rapidly distended and her breathing shallow and quick, and her expression was most anxious. She was stimulated freely but in about an hour she died.

At the post-mortem examination on opening the abdomen the great omentum was found to be slightly adherent to the anterior abdominal wall and firmly so to the coils beneath. The stomach contents filled the right half of the abdominal cavity and pelvis. An abscess between the coils of small intestine occupied the right iliac fossa, extending downwards into the pelvis and upwards along the ascending colon. Elsewhere there were signs of more recent peritonitis. The vermiform appendix was healthy. On examining the stomach there was found on the anterior surface near the pylorus a perforated ulcer, oval in shape and three-quarters of an inch long. The peritoneal margin was ragged and apparently recently destroyed, but the mucous edge was smooth. The ulcer was not terraced. Neither was it thickened nor adherent to neighbouring structures. No other ulcers were to be found.

10 were under 31 years of age and six were under 40 years. In its circumscribed form it has been mistaken for myomatous or fibro-myomatous and cystic tumour of the vagina. When ulceration has occurred and the disease has extended it has been mistaken for carcinoma, tubercle, and syphilis. The prognosis is essentially bad, as the disease is generally not seen in time. According to Dr. Otto Seitz, of all known cases only three patients have recovered.

In the case which occurred in the Munich Klinik the patient, a multipara, was 41 years of age. The principal symptoms were severe hæmorrhage, accompanied by fœtid discharge and pain on micturition, attended by emaciation. The inguinal glands at either side were enlarged. There was no evidence of any heart or lung complication. The growth appeared from the middle line of the posterior wall, occupying its entire length, easily bleeding, and with a rough fissured surface; there was infiltration of the recto-vaginal septum. The growth had extended so far in the paravaginal tissue as to make a radical operation impossible. A partial operation, by enucleation and cautery, was attempted, but two months afterwards there was a return of the growth, with partial involvement of the glands.

My own case, which I brought before the British Gynæcological Society, was that of a woman aged 44 years. She had been married for 23 years and her last pregnancy—there having been no miscarriage in the interval—was 22 years previously. She first noticed a vaginal discharge in May, 1901, and this had continued almost constantly up to the time of my seeing her in November, 1901. She had run down in her general health and had lost weight. Until I saw her she had refused to allow any examination to be made. On attempting a digital one by the vagina, I found a considerable mass filling the lower part of the canal and bleeding so freely that I had to desist. I was able, however, to trace the growth to the vaginal wall, but did not discover at the time that the cervix uteri was not involved. Indeed, my own impression was that it was a carcinomatous mass sprouting from the cervix. On anæsthetising her I found that the uterine neck was completely concealed by the ulcerating mass and that it was in no way involved, while the lateral and posterior walls of the vagina were perfectly healthy. I further found that the growth was connected by a broad base, more or less pedunculated, to the anterior wall of the vagina, not involving the external genitalia. The inguinal glands were quite free. I adopted the following plan for its removal. I surrounded the entire tumour by the thick wire rope, tightening this on it gradually. Behind this I placed the blades of a Billroth's clamp and next removed the growth with scissors. With a Paquelin's cautery I then cauterised down to the blades of the clamp, which I was now able to remove. I next made two circular incisions into the healthy vaginal wall at either and exposed a healthy subjacent raw surface, being careful of the bladder. When all bleeding had been arrested, with a Paquelin blade I again cauterised the whole of this surface and raising the healthy vaginal mucous membrane at either side for a short distance, brought the clean edges together with Cumol gut, leaving only a single linear incision in the anterior vaginal wall. The entire operation was thoroughly aseptic. The vagina was kept tamponned with sterilised iodoform gauze and the urine was drawn off for some 10 days after operation. The wound united by primary union. Up to the present everything has been most satisfactory. I am indebted to Mr. J. H. Targett for a microscopical report on the specimen and for the section from which the accompanying drawing was made.



Spindle-celled sarcoma of the vagina.

*Report on the growth by* Mr. J. H. TARGETT.—This growth is a spindle-celled sarcoma of the vagina. The surface is ulcerated and covered with necrotic material. Among the spindle cells there are a few larger polynuclear cells.

Harley-street, W.

# ON HÆMOLYSINS PRODUCED BY CERTAIN BACTERIA.

BY ALDO CASTELLANI, M.D.,
ASSISTANT, MEDICAL CLINIC, FLORENCE.

(*From the Bacteriological Department, Jenner Institute of Preventive Medicine.*)

ALTHOUGH the production of hæmolytic substances in the cultures of certain bacteria (bacillus typhi, bacillus coli, and bacillus dysenteriæ of Kruse) was demonstrated originally by Ehrlich[1] and subsequently by Bullock and Hunter,[2] we are indebted to Neisser and Wechsberg[3] for the first complete research on the subject. The last-mentioned observers showed that the filtered as well as unfiltered broth cultures of several races of staphylococcus pyogenes aureus evinced marked hæmolytic properties on the erythrocytes of the rabbit's blood. The formation of hæmolysins was found to reach its maximum in cultures of from 10 to 15 days old, and decreased afterwards by degrees. These observations were soon confirmed and amplified—e.g., by Baiardi[4] and by Lubenau,[5] &c. It has been recently stated by E. and P. Levy[6] that hæmolysins are produced by the bacillus typhi, although this has been denied by Pane,[7] and, on the other hand, has been corroborated by Macfadyen and Rowland.[8]

On account of this difference of opinion I have been led to repeat the experiments of E. and P. Levy. At the same time I considered that it would be of value to carry out a parallel series of experiments with the colon bacillus and the dysentery bacillus of Kruse in order to determine how far they compared in their action with the typhoid bacillus with which they are so closely related. The dysentery bacillus is regarded by Kruse as most probably the cause of the European form of dysentery. It is a rather short and plump bacillus, is non-motile and does not stain by Gram's method. On all culture media its growth resembles that of the typhoid bacillus, it does not produce gas in sugar media and it does not coagulate milk. It is strongly agglutinated by the serum of patients suffering from dysentery. It need hardly be said that the European form of dysentery is in many respects quite different from the tropical form. Further particulars with regard to this interesting organism will be found in the original paper by Kruse[9] as well as in a paper by myself.[10]

As regards the technique I have followed in its general outline the well-known methods of Neisser and Wechsberg. A certain number of faintly alkaline broth flasks were prepared and inoculated with bacillus typhi, bacillus dysenteriæ, and two different races of bacillus coli, which I shall term I. and II. The cultures were incubated for varying periods—e.g., three days, five days, and longer—they were extract were injected subcutaneously into the forearm. Two seconds after the injection the patient complained of a sudden spasmodic contraction of the muscles of the arm and fingers. On feeling the pulse at the radial immediately after injection I was alarmed to find that it almost disappeared for a few seconds. That this symptom was due to the local muscular spasm with which it was coincident is confirmed by the fact that the arterial pulse in the left radial was found to be full and vigorous. 12 minutes after injection the arterial pressure was found to be 150 millimetres of mercury and the pulse-rate was 85. Previously to injection the patient had complained of feeling uncomfortably hot and a couple of minutes afterwards he spontaneously remarked that "all the heat seemed to have gone inside." Two hours after the injection the pulse-rate was 89 and the pulse itself was much stronger and fuller. The patient still complained of feeling cold at the extremities. Three hours after injection the pulse-rate was 95 and the blood-pressure 135 millimetres of mercury. There were some pain and localised swelling at the site of the injection. There was marked diuresis during the 24 hours succeeding the injection; the urine was acid with a specific gravity of 1010. There was no glycosuria, an effect frequently noticed after suprarenal injection. I have taken considerable quantities of the pressor substance by the mouth but have never been able to record any result, although the substance is unaltered by peptic digestion and is dialysable. The pressor substance would appear to be proteid in nature. It is precipitated from salt solution by trichloracetic acid, gives biuret, xanthoproteic and Millon's reactions. It is not precipitated by saturation with a neutral salt, it is unaffected by peptic but decomposed by prolonged tryptic digestion. The iodine found in the pituitary is not apparently in combination with the pressor substance. Its cardiac, vascular, and diuretic action would indicate that it may prove to be of service in cases of heart disease.

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A CASE OF RECOVERY AFTER VERY EXTENSIVE INJURIES.

By MONTAGUE TENCH, M.D. BRUX.,

MEDICAL OFFICER TO GREAT DUNMOW INFIRMARY.

As an example of extensive injuries followed by complete recovery the following case may prove of interest.

In the course of 1901 a man, aged 55 years, a farm labourer, was knocked down and run over by the barn works of a threshing machine, drawn by four horses which he had been leading and which had taken fright. Both wheels on the near side passed diagonally across his pelvis and chest while he lay on his left side. When picked up and admitted to Great Dunmow Infirmary he was collapsed and pulseless and appeared to be in a dying condition. He recovered consciousness within a couple of hours and the following injuries were recognised. Both iliac bones were broken off above the pelvic brim, being freely moveable with coarse crepitus. There was no injury to the bladder or the urethra, but the torn rectum was extruded through a rent reaching from the anus to the scrotum rather to the left of the middle line. Large hæmatomata extended from the buttocks down the outer side of both thighs to their middle. Several ribs on both sides were broken, so that the sternum was protruded and moveable with crepitus. Surgical emphysema developed the same evening on both sides of the trunk and on both arms to the wrist, though there was no external breach of surface and no hæmoptysis. The left clavicle was extensively comminuted, otherwise the limbs and head escaped.

Extensive sloughing of the back and buttocks occurred during the ensuing six to eight weeks, laying bare the sacrum, and the hæmatomata, which had suppurated, discharged through an area eight inches in diameter over and above the sacrum. Pus and sloughs were discharged for 10 weeks.

The patient left the infirmary six months after the accident walking without limping, and is now contemplating resuming his work.

The temperature rose to 102° F. within the first week with the onset of suppuration, and assumed a hectic type while the discharge continued. Considerable wasting occurred during this time, but was rapidly made good afterwards. There was no indication of injury to internal organs other than that inferred from the general emphysema.

### QUININE AS A DRESSING.

By J. REID, M.A., M.D., C.M. ABERD.

QUININE has been used in lotion for various diseases, but combined with cod-liver oil externally I do not know of any reference to the subject. I have used it with good results (one drachm to eight ounces in emulsion, to be shaken up before being used) in tertiary and rheumatic ulcers of the leg and for ordinary ulcers, in a case of gangrene of the skin, and after a burn, where a large surface (about a foot square) formed a slough and had to be removed as ulceration loosened the thick slough. All wounds took on a healthy and kindly action, and the pus from the sloughing derma smelled sweet and contained a limited number of cocci. I do not know that the dressing has anything to recommend it in the way of cheapness or of odour, but it has the advantage of supplying a weakened system with an oily food and a tonic drug. For intertrigo I have used it with good effects if not long required. For eczema it seemed to act well if stomach troubles were seen to.

## ST. MARY'S HOSPITAL.

### A CASE OF TRAUMATIC RUPTURE OF THE PROSTATIC URETHRA; COMPOUND FRACTURE OF BOTH LEGS; OPERATION; RECOVERY.

(Under the care of Mr. EDMUND OWEN.)

IN the following case the urethra was ruptured by external injury in an unusual situation. The most common site of rupture when occasioned by external violence is certainly the membranous portion of the urethra, but in this case the urethra was torn behind the posterior (superior) layer of the triangular ligament. This lesion is not very rarely produced by fracture of the pelvis, though in the case recorded below no signs of fractured pelvis were present. For the notes of the case we are indebted to Mr. W. J. Finlayson, dresser.

On the afternoon of Oct. 21st, 1901, some children were playing in the timber-yard of an undertaker, when they upset a pile of coffin-lids which fell upon them, killing one of them. As a result of this accident, a boy, aged seven years, was brought into St. Mary's Hospital with compound fracture of each tibia, and in a state of serious *collapse*. The house surgeon, Mr. V. Nesfield, at once took him into the theatre, and, under the influence of chloroform, cut down on to the right tibia, clearing dirt and blood-clot from the wound; then, having sutured the periosteum which had been extensively stripped up, he inserted a drainage-tube and dressed and fixed the limb. He treated the left tibia in the same way (this fracture was comminuted as well as compound, and the fibula was also broken and exposed). Marks of severe bruising were noticed over the lower part of the abdomen.

When the house surgeon saw the boy at night he found that some blood had escaped from the urethra, but that no urine had been passed. He, therefore, tried to introduce a catheter, but though he could not make it enter the bladder, Although on the first day of the illness the probability of an attack of biliary colic was entertained I need hardly dilate on the symptoms of the following days, for they were sufficiently clear to justify a diagnosis of appendicitis. The detection of a collection of fluid in the pelvis, continuous with a dull area in the right iliac fossa, is not infrequently found in that condition. The perforation of an ulcer of the anterior gastric wall usually produces general peritonitis, with a rapidly fatal termination. The ulcer appeared to be acute in its formation and probably the perforation was slow in its completion, an example of the "subacute" perforations. The escaped fluid no doubt took such a course as has been well described by Mr. B. G. A. Moynihan in a published paper on perforated duodenal ulcers.[1] In this case the fluid, having passed over the edge of the transverse meso-colon and along the ascending colon to the iliac fossa, became shut off from the general peritoneal cavity by the great omentum which formed an effective lid for the suppurating cavity. Whether the final shock was due to a more complete perforation of the ulcer or due to a bursting of the iliac abscess into the general peritoneal cavity, the complete gastric perforation having already occurred, I am not prepared to say.

Finally, I wish to express my indebtedness to Mr. E. Down for the notes of the case previously to admission, and to Mr. G. Thom, under whose care the patient was admitted, for his kind permission to record the case.

# THE MEDICINAL USE OF THE PRESSOR SUBSTANCE OF THE PITUITARY BODY.

BY F. GOLLA,
LATE DEMY OF MAGDALEN COLLEGE, OXFORD.

*(From the St. George's Hospital Physiological Laboratory.)*

THE physiological effect of injections of pituitary extract has been worked out in the last few years by a number of observers. Oliver and Schäfer[2] demonstrated that an extract of the pituitary body caused a marked rise of blood-pressure when intravenously injected, and they were able to show that this effect was due to a contraction of the blood-vessels and augmentation of the cardiac contraction which persisted after destruction of the central nervous system. They pointed out that it differed in its action from suprarenal extract inasmuch as a definite slowing replaces the accelerating action on the heart of a suprarenal injection after section of the vagi. Howell[3] tested the effects of both the anterior lobe and the infundibular body when injected in saline extracts. He found little change with injection of the hypophysis alone, but injection of the infundibular body caused a marked slowing of the heart with the vagi intact, and with the vagi divided or after atropin the slowing of the heart-beat was less pronounced, though in both cases there was a rise of blood-pressure. Cyon[4] also obtained a rise of blood-pressure and slowing of the pulse from injection of pituitary extract. He showed that section of the vagi either before or after injection had little influence on the results obtained and that atropin injections, unless in very large quantities, did not inhibit the retardation produced by the pituitary extract. Cleghorn[5] was able to obtain slowing of the isolated mammalian heart on perfusion of pituitary extract. More recently Schäfer and Vincent[6] were able to demonstrate the existence of two substances in the infundibular part of the pituitary gland having distinct physiological properties, one of these producing a rise and the other a fall of blood-pressure. These two bodies they distinguished as the *pressor* and *depressor* substances. Of these they found that the pressor substance is soluble in salt solution and insoluble in alcohol and ether, whilst the depressor substance is soluble in all three. The active substances are not destroyed by boiling. The pressor substance was found to produce its action on the heart and the peripheral arteries; its action is prolonged and during its period of action a second dose is inactive or nearly so. They were able to obtain the same retardation of the cardiac mechanism as that produced by injection of pituitary extract in the previously mentioned experiments. In a recent communication Schäfer and Magnus[7] admit that the depressor action of alcoholic extracts of the pituitary cannot be regarded as of a specific nature. They find that the pressor substance of the pituitary body, unlike suprarenal extract, causes no diminution in volume of the kidney when injected intravenously. The injection is followed by a diminution in volume of the spleen, intestines, and extremities with an increase in volume of the kidneys and a prolonged and pronounced diuresis which, however, lasts for a shorter period than the change in volume of the kidney.

The medicinal use of pituitary extracts has hitherto been attended with no very pronounced results. Cyon[8] considered that the hypophysis was able to act vicariously with the thyroid. He also attributed to it a specific action on the vagus as far as its cardiac mechanism is concerned. Lo Monaco and van Rynbuhr[9] have, however, recently disproved Cyon's statement that, after removal of the pituitary, excitation of the cardiac vagus centre is ineffectual and confirm the view of Friedman and Maas that removal of the pituitary is not followed by any morbid results. Schiff[10] found that administration of pituitary extract, though it had no effect on the metabolism of a young man, caused in an old man and a patient suffering from acromegaly marked increase in the phosphorus excretion by the urine and fæces. There was no corresponding increase in the nitrogenous metabolism, and one may conclude that the pituitary influences chiefly the metabolism of tissues rich in phosphorus and poor in nitrogen. These results are confirmatory of the belief in the causal connexion between disease of the pituitary and acromegaly. It would also seem possible that administration of pituitary extract might have a beneficial result in cases of myositis ossificans. Marinesco[11] was unable to effect any improvement of the condition of the extremities in three pronounced cases of acromegaly, but the headaches and neuralgic pains in the limbs were much relieved. Broadbent found great improvement in the psychical condition of patients suffering from acromegaly from treatment with pituitary extract. Rolleston[12] obtained a lasting improvement in the case of a woman who had suffered for three years from acromegaly which was permanent after the pituitary treatment had been suspended. The only cases of subcutaneous injection of pituitary extract that I have been able to find are those of Cyon, where he obtained a marked improvement in cardiac disease, and of Mairet and Bosc[13] who found that injection in a case of epilepsy was without result.

A consideration of the physiological properties of the pressor substance isolated by Schäfer and Vincent led me to try its effects on the human subject. Its slowing action on the heart beat, unlike that of digitalis, appears to be due to a prolongation of the systole rather than of the diastole. The pressor substance would appear to act exclusively on the sarcoplasm. I have been unable to obtain any marked effect on the muscles of amphibia rich in the rapidly contracting anisotropic elements such as the gastrocnemius. For clinical purposes the pressor substance purified by repeated washing of the alcoholic precipitate with ether obtained from 80 grains of the dried infundibulum was dissolved in 30 minims of normal saline. I found on injecting three minims of this solution into the mucous membrane of the lower jaw that a definite local vaso-constriction resulted; the mucous membrane remained blanched for about three-quarters of an hour for a considerable area round the point of injection. On injecting five minims subcutaneously into my right forearm there was a perceptible pallor of the finger nails for a few minutes. The pulse-rate fell from 95 to 84, and the wave was appreciably fuller. A subcutaneous injection was next made on a patient suffering from advanced Addison's disease under the care of Dr. H. D. Rolleston. The blood-pressure in the radial artery before injection was found to be 120 millimetres of mercury by means of the Hill and Barnard sphygmometer. The pulse-rate was 100. Eight minims of the saline of the ulcer and was left in the upper part of the wound, the lower portion of which was closed with salmon-gut sutures. The patient was infused during the operation with two pints of normal saline solution containing 10 minims of liquor strychninæ and an ounce of brandy. She made an uneventful recovery and left the hospital on Jan. 1st, 1902.

*Remarks by* Mr. HITCHINS.—The following points are of interest. The occurrence of a perforated gastric ulcer in two members of the same family and of the same sex. In each case the ulcers were close to the lesser curvature near its cardiac end, the most common situation being near the pylorus. In the first case perforation took place three and a half hours after the ingestion of food, and in the second case a similar time had elapsed after a meal, perforation usually taking place at a short interval after a meal. The first case illustrates the chance of recovery even where operation does not take place for many hours after perforation—in this instance accompanied by considerable extravasation of food with resulting peritonitis. Free gas was present in the first case with diminution of the liver dulness; in the second case no free gas was present and there was no absence or diminution of the liver dulness. It is rare for perforation to occur at so young an age as that of 16 years. Both patients had good teeth I believe the second case to be one of the youngest recorded. I have to thank Mr. Whipple and Mr. Lucy for kindly permitting me to record the cases, and Dr. Pethybridge for notes on the cases up to the time of their admission.

# Medical Societies.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

### *Two Cases of Ligature of the Left Carotid for Aneurysm of the Arch of the Aorta.*

A MEETING of this society was held on Feb. 11th, Dr. F. W. PAVY, the President, being in the chair.

Mr. CHRISTOPHER HEATH read a paper on two cases of Ligature of the Left Carotid for Aneurysm of the Arch of the Aorta, and showed post-mortem specimens of four cases. The cases reported were the sixth and seventh in which Mr. Heath had performed the operation. The sixth case was in a woman, aged 61 years, under the care of Dr. A. H. Robinson in the Mile End Infirmary, where she was admitted in July, 1890, with all the symptoms of aneurysm of the arch of the aorta. She was kept in bed and had large doses of iodide of potassium for many weeks, but no alteration in the pulsation resulted. She always sat up in bed with the knees drawn up and her head resting upon them. On attempting to lean back against the pillows the dyspnœa increased and inspiration became stridulous. The left carotid was tied without an anæsthetic on Nov. 16th, 1890. On Nov. 19th the respiration, which had been distinctly noisy, was now unaccompanied by the least noise and the patient was able to recline against her pillows. On Nov 22nd she was able to sleep for seven hours consecutively. In January, 1891, there was some return of pain in the right shoulder. In February the pulsating tumour above the sternum had decreased and the patient was able to lie and to sleep in any position. She continued to improve and was discharged at her own request on August 8th She was admitted to the London Hospital on Sept. 3rd, when the pulsating tumour could be just felt above the clavicle, and she died suddenly on Nov. 29th, more than a year after the operation. The seventh case was that of a man, aged 36 years, admitted into University College Hospital under the care of Dr. F. T. Roberts on Nov. 4th, 1898, with aneurysm of the arch. The physical signs were well marked and included "tracheal tugging" and a blowing systolic sound over the aneurysm. The lungs were examined and found to be healthy During November, December, and January the patient had severe attacks of pain in the shoulders, back, and neck. The aneurysm at first diminished, but in January it increased in size and definite swelling and pulsation appeared beneath the pectoral below the right clavicle. Mr. Heath tied the left carotid with silk under eucaine β on Jan 18th, 1899. On the 20th the pulsation was distinctly less marked and daily improvement was noted till Feb. 1st, when the patient returned to the medical ward with the operation wound healed. The pulsation in the aneurysm was now much less distinct and the patient was free from pain and had slept well since Jan. 20th. On Feb. 16th the patient had pain in his chest and next day his temperature went up to 103° F. and he rapidly developed all the symptoms of acute phthisis and died on March 21st. The aneurysm gave no trouble and was daily less evident. The specimens shown were four in number, one from a man under the care of Dr. Cockle on whom Mr. Heath tied the left carotid in February, 1872, and who greatly improved for a twelvemonth, when he resumed his hard agricultural labour and the aneurysm began to grow and eventually burst four and a half years after the operation. In this case the necropsy was made three days after death in very hot weather and the decomposed clots were unfortunately washed away. The second specimen was from a case of a man, aged 38 years, in whom Mr. Heath had tied the left carotid on March 8th, 1890, and the patient died suddenly on May 12th. The aneurysm was filled with laminated clot. The third specimen was from Case 6 and showed an aneurysm of the size of an orange almost completely filled with laminated clot. The fourth specimen was from Case 7 and showed an aneurysm of the arch of the size of a clenched fist and a second small aneurysm of the root of the innominate, both of which were nearly filled with laminated clot, the centre of the larger being occupied with soft clot. Mr. Heath maintained that ligature of the left carotid undoubtedly produced an immediate effect upon aneurysm of the arch and discussed the theories which had been proposed to explain the formation of laminated clot in the sac. He thought that the ultimate solidification of the aneurysm, though its only method of cure, accounted for the sudden deaths which occasionally occurred some months later, owing partly to pressure effects and partly to the induction of syncope.

Mr. A. CARLESS mentioned the case of a woman, aged 40 years, who for five months before coming under observation had had pain in the right shoulder, arm, and neck, with dysphonia and dysphagia. She had a brassy cough. There was no specific history and she had had two healthy children. When admitted to hospital the chest wall was pushed forward at the level of the first and second ribs on each side. There was a swelling below the left sterno-mastoid muscle. Both the temporal and radial artery on the left side were diminished in size. While under observation she had several attacks of syncope and the aneurysmal sac seemed to become more tense. The left carotid was tied and for a few days after the operation there was a slight increase in tension of the sac and there was also slight loss of power on the left side of the face and the left side of the tongue. A few days later these symptoms disappeared, the dyspnœa became less, and the pulsation diminished 24 days after the first operation the first part of the subclavian artery was tied; shortly after this she had a bad attack of cardiac failure and cough which was relieved by the use of digitalis. Six months later very little pulsation could be felt above the clavicles, and for three years she was able to go about and do her work with comfort. She died suddenly from rupture of the aneurysm into the left pleural cavity At the necropsy the aneurysm was found not to be sacculated. The left carotid and subclavian arteries were small and contracted. The conditions under which he considered the operation advisable were when the pulsation was marked on the left side and involved the root of the left carotid artery.

Dr. F. T. ROBERTS said that the main point of discussion was under what circumstances the carotid and subclavian vessels should be tied. He considered that the two chief causes of aneurysm were heavy work and alcohol, and he was also of the opinion that smoking had a deleterious effect on the walls of the vessels. The chief indication for operation was pain, while aortic regurgitation and degeneration of the arteries were unfavourable to operation.

Mr. R. BARWELL, in discussing the suitability of cases for operation, said that in those cases in which the dilatation of the aorta was symmetrical clot was not likely to form even if the vessels were tied, whereas if the aneurysm was sacculated clot was much more likely to form. He also agreed with Mr. Heath that the clot did not extend down from the ligature but was formed in the sac itself near the exit of the vessel from the sac. He considered that it was frequently advisable to tie the right carotid and right subclavian rather than the vessels on the left side—indications which vessel should be tied being derived from a consideration of the vocal cords and the state of the pupil. He he drew off a little blood-stained urine. As the boy was recovering somewhat from the shock, and as there did not appear to him to be urgent need for further active interference, Mr. Nesfield decided to leave the boy quiet for the night.

Next day Mr. Owen saw the boy, and, finding that no urine had been passed, he had him at once taken into the theatre. The bladder was evidently distended, and there was great tenderness all over the hypogastric region. There was slight fulness in the perineum, and some blood was oozing from the meatus urinarius. As it was impossible to pass a catheter, Mr. Owen opened the urethra in the perineum, but he found there neither blood nor urine; and as he still could not find the way into the bladder, he had the boy placed flat, and made an incision through the lower part of the linea alba, so as to expose the front of the bladder below the peritoneum. This being done, and before the bladder was reached, blood and urine freely escaped, showing that leakage had occurred into the pelvis. But the bladder was so much distended and was so firm that it was evident that the leakage was not from it. An incision was then made into the bladder, when urine and clots escaped. The pool of stagnant urine on the floor of the pelvis was drained by making an incision through the pelvic fascia and levator ani at the side of the prostate, and passing a large, soft tube through it into the wound already made in the perineum. The bladder and pelvis were then washed out with hot water. The boy was so extremely ill when upon the table that it was impossible to make search for the exact position of the rent; but inasmuch as no instrument could be passed into the bladder whilst there was escape of urine into the pelvis (but not into the perineum), there could be no doubt but that the rupture was behind the triangular ligament. Had the neck of the bladder itself been torn the bladder would probably not have remained full of urine under pressure. The rent, therefore, must have been between the neck of the bladder and the triangular ligament. To the surprise of all concerned the boy recovered. For a time some of the urine passed by the suprapubic wound and some by the perineal drain. Eight days after the operation Mr. Nesfield placed the boy under chloroform for the sake of rearranging the dressings of the legs, and he took that opportunity of exploring the bladder. He then found that he could pass his finger through the suprapubic wound and out through the perineal incision, and he formed the opinion that the rupture was in the prostatic portion of the urethra. With his finger thus in the bladder, he succeeded in introducing a steel bougie through the urethra and into the bladder. Gradually the openings closed and the urine flowed more abundantly by the proper route. From time to time a No. 7 English bougie has been passed to give assurance that no contraction is taking place, and up to the present all the urine has come the right way and the boy is convalescent.

## SOUTH DEVON AND EAST CORNWALL HOSPITAL.

### TWO CASES OF PERFORATING GASTRIC ULCER OCCURRING IN SISTERS; OPERATION; RECOVERY.

(Under the care of Mr. R. H LUCY and Mr. WHIPPLE.)

THE cases of perforating gastric ulcer treated by operation which have been recorded in THE LANCET within recent years have been very numerous, but in nearly every case there is some special point of interest or importance. The two cases recorded below are remarkable in that two sisters suffered from perforation of gastric ulcer. Inasmuch as such an occurrence, so far as we are aware, has not been recorded before, we must look upon it as little more than a coincidence, though the same predisposing factors were probably present in the two cases. Instances have been observed in which two members of the same family have suffered from ulceration of the stomach,[1] but without perforation In the second case recorded below the patient was only 16 years old. An instance of perforation in a younger child has been described[2] in which a child, 13 years of age, died from a perforating gastric ulcer. For the notes of the case we are indebted to Mr. F. C. Hitchins, late house surgeon.

CASE 1.—A young woman, aged 20 years, was admitted into the South Devon and East Cornwall Hospital on March 9th, 1900, under the care of Mr. R. H. Lucy. On the 8th the patient was at work in her usual health, when at about 11.30 A.M. she was seized with an attack of sudden severe pain in the epigastrium. She was slightly sick once and was taken home. The pain continued with no improvement until the evening. About two years previously she had been treated for dyspepsia, but recently she had not complained of anything definite. She had never had any hæmatemesis. At 10 P.M. Dr. W. L. Pethybridge saw the patient. She was very anæmic and had an anxious expression. The pulse was 120 and feeble and the temperature was 100° F. The abdomen was generally distended and there was great tenderness in the epigastrium and the left hypochondrium. There was resonance everywhere with the exception of some slight dulness in the right flank. The liver dulness was distinctly diminished. A diagnosis of perforated gastric ulcer was made and the patient was advised to enter the hospital at once for operation, but she declined to do so. A quarter of a grain of morphia was injected. On the next morning at 10 o'clock she was seen again, when the pulse had increased to 140 and the liver dulness was still further diminished. She now consented to the performance of an operation and was removed to the hospital. At 12.30 P.M. the abdomen was opened under chloroform. Free gas at once escaped and a perforated ulcer of the size of a shilling was found on the anterior surface of the stomach close to the cardiac end of the lesser curvature. The edges were very indurated, the aperture being so large and the patient's general condition so bad that it was thought inadvisable to attempt to suture it. The abdomen was flushed out with hot saline solution and the contents of the stomach, which were free in the peritoneal cavity and included a large piece of orange, were evacuated. A rubber drainage-tube was passed through the ulcer into the stomach, iodoform gauze being packed round the tube. The lower portion of the wound was then closed with salmon-gut sutures. During the operation the patient was infused with six pints of saline solution containing an ounce of brandy. She remained in a very critical condition for 48 hours after the operation, after which she began slowly to improve. Two days later the gauze round the drainage-tube was removed and was replaced by fresh gauze. On the 14th the drainage-tube was removed and a No. 12 Jacques catheter was passed in its place. On the 19th the Jacques catheter was removed. On the 30th the wound, which had suppurated rather freely, was quite sound. The patient was discharged from the hospital on May 1st. She could now take chicken, mutton, &c., is free from pain, and feels quite well.

CASE 2.—A girl, aged 16 years, the sister of the patient in the preceding case, was admitted into the South Devon and East Cornwall Hospital on Nov. 16th, 1901, under the care of Mr. Whipple. The patient had complained of pain after taking food and of shortness of breath with occasional vomiting for three months. There had been no hæmatemesis. On Nov. 16th she had her dinner, consisting of meat and vegetables, at 1.45 P.M., after which she worked at a sewing-machine for about two hours. At 5.15 P.M., when sitting quietly in a chair, she was suddenly seized with acute pain in the epigastrium and left side which continued until 8 P.M., when she was attended by Dr. Pethybridge. There had been no vomiting. When seen her face was pale and anxious-looking, her legs were drawn up, the respirations were rapid and shallow, and the pulse was 126 and of fair volume. The abdomen was distended in its lower half, tender all over, and moved very slightly with respiration. There was dulness extending from the pubes nearly to the umbilicus; this, however, proved to be due to a distended bladder. The patient was sent into the hospital with a diagnosis of perforated gastric ulcer. At 10 P.M. the abdomen was opened under chloroform followed by ether. On opening the general peritoneal cavity fluid, but no free gas, escaped. A perforated ulcer of the size of a sixpence was found at the extreme cardiac end of the stomach on its posterior surface high up under the diaphragm. In order to expose the ulcer considerable traction had to be made on the stomach. The ulcer was round and clear-cut with indurated edges. Semi-digested food escaped through the opening. This was removed with swabs, the edges of the ulcer being approximated with considerable difficulty by means of Lembert catgut sutures passed about a quarter of an inch beyond the margins of the ulcer. The sutures tended to cut out when being tightened. A gauze drain was passed down to the seat enlargement of the epiphyses which was present in the first case made it probable that the case was one of rickets. The term "osteomalacia" should not be used for this class of cases.

---

[1] THE LANCET, Oct. 9th, 1858, p. 370.

[2] Medical Times and Gazette, 1872, vol. i., p. 220.

Dr. W. ESSEX WYNTER showed three cases of Chronic Œdema. The first patient was a single woman, aged 23 years, who had enjoyed good health till November, 1900, when she developed a cough which lasted through the winter. For the past 10 years the patient had complained of attacks of misty vision lasting one or two minutes which had lately increased in frequency. Three years ago there was some swelling of the lips and tongue noticed chiefly on rising and lasting two months. The swelling of the face and legs appeared to have come on gradually and to have been notably worse since May, 1901, especially after walking or long standing, the legs being at times so stiff that she could only flex them with difficulty. In the mornings the swelling was softer and less distinct. The swelling of the face was noticed a few months earlier than in the legs, especially about the right eye. The general health appeared to have been unaffected and there had been no pain. The thoracic and abdominal organs appeared to be normal. The reflexes were brisk. The urine was of a dark amber colour and was cloudy and acid; its specific gravity was 1020; no albumin or sugar was present. Some improvement was noted in the degree of the swelling of the face and the legs;—it varied, but it did not entirely disappear with massage, and subsequently it had been as much as at first. With the disappearance of the hardness pitting could be more easily obtained. The temperature was normal throughout and the bowels acted regularly. Thyroid extract had been given freely for three months without effect. The second case was that of a girl, aged 17 years, who had had erysipelas seven years ago. The mother stated that from infancy the patient's legs were very "fat." About three months ago the face and hands were noticed to be swollen on rising and the enlargement of the legs increased. The swelling continued to increase daily and became more persistent. Recently she had noticed some dyspnœa on exertion and polyuria; otherwise the general health had been good. The face was pale and was uniformly swollen, the eyes being half closed; the hands also were swollen but were not distorted in shape; and dimples over the knuckles were well marked. The legs were uniformly enlarged and were very firm, only pitting slightly on hard and sustained pressure, the skin not being white or shiny. The thoracic and abdominal organs appeared to be normal. The urine was pale, clear, alkaline, of specific gravity 1009, and was free from albumin and sugar. The pulse ranged from 60 to 70 and was full and regular. There was a marked depression over the trachea and the rings could be readily traced, the thyroid isthmus being apparently absent. Thyroid tabloids had been increased from one to three daily. While lying in bed there was at first marked improvement, but on the patient getting about the measurements of the legs had returned nearly to their original dimensions, but were not so hard. The temperature had been fairly normal and the bowels had acted about once a day. There was an increase of seven pounds in weight in three weeks. The third case was that of a female, aged 25 years, who stated that she had never felt brisk and active but had not had any definite illness. For eight years she had suffered with diarrhœa, the bowels sometimes acting every quarter of an hour, accompanied with pain and prolapsus ani. She had suffered with severe depression. There had been menorrhagia of late with anæmia. The complexion was of a peculiar tallow-white and the face was somewhat puffy, with drooping of the lower lids and marked thickening of the upper lip, giving the appearance of a facial diplegia or Erb's paralysis; the muscles, however, retained the power of voluntary movement. The hair was rather thin over the forehead. The patient was full-necked and her speech was slow and monotonous. Knee-jerks were present. The diarrhœa was checked, but after a month the general condition remained unaltered. Five-grain doses of thyroid extract were ordered daily and rapid improvement ensued.

Mr. T. H. KELLOCK showed a case of Actinomycosis of the Tongue after Treatment by Cauterisation and Iodide of Potassium. The patient, a youth, aged 18 years, who had lived all his life in London, was admitted to hospital on Nov. 26th, 1901, for hæmatocele of the spermatic cord for which an operation was performed on Dec. 4th. On the 31st, two days before he was going to leave the hospital, he drew attention to a swelling on his tongue which he stated he had noticed that day for the first time. On examination a soft swelling of about the size of a small pea was seen on the dorsum of the tongue on the right side, rather yellowish in colour, and a somewhat similar swelling on the right side and slightly under the tongue. It was painless and not tender. An incision was made into it, and a little blood and pus were let out, which contained many yellowish-white granules. These, under the microscope and on cultivation, showed masses of streptothrix. On the following day, under an anæsthetic, the swellings were both freely incised, were scraped out with a spoon, and then were freely treated with the actual cautery. A little sloughing followed this, but it soon cleared up and the patient was discharged from the hospital on Jan. 9th, 1902. Two days after the operation he was given a mixture containing eight grains of iodide of potassium three times a day, which was gradually increased to 20 grains.

Dr. BERNARD E. POTTER showed a case of Nodding Spasm in a child, aged nine and a half months, who had suffered from nodding movements for four months. The child had always lived in very dark rooms with the exception of the two months of August and September, 1901, when the parents took her away with them to Norfolk. They returned with her about the middle of September, and the nodding movements began a month later, the child being then five and a half months old. Teething began at the age of five months. The child had been breast-fed and had had no other ailment. She was well nourished and had never had convulsions. The mother's labour had been natural and no instruments were used. The movements were almost entirely in the vertical direction. Soon after these head movements began a rotatory nystagmus in both eyes was noticed. The interest of the case lay in the following facts—that the movements began almost immediately after the commencement of dentition, that the change from the light rooms in Norfolk to the present dark ones in London appeared to have influenced the child, and that the movements were nodding in character and not from side to side as is more commonly the case.—Dr. ARTHUR F. VOELCKER said that the nystagmus in these cases differed from that seen in disseminated sclerosis in that the nystagmus was often of a convergent type.—Dr. CAUTLEY said that the etiology of these cases was of interest. He did not believe that they were due to teething, to rickets, or to dark rooms. He said that the prognosis was good except in those cases associated with microcephalus.

Mr. SPENCER showed a case of Scirrhous or Atrophic Cancer of the Tongue. The patient was a thin man, aged 72 years. He came to the hospital in November, 1901, complaining of increasing difficulty in swallowing and speaking owing to fixation of the tongue. Since then he had been taking iodide of potassium and mercury, but the disease had progressed and he required now 10 grains of compound pill of soap every night to obtain sleep. The patient spoke and swallowed with difficulty. The tongue was seen to be depressed to the level of the floor of the mouth and fixed, especially as regards its anterior half, whilst the epithelial surface was unaltered except as regards puckering, and there was no evidence of previous inflammation or ulceration. The tongue felt like a board and formed the surface of a densely hard mass to be felt bulging below the jaw and fixed to the horizontal rami, especially on the right side, on which side also the submaxillary glands appeared to be already involved in the tumour. The case appeared to be one of the rare variety of malignant disease of the tongue called scirrhous or atrophic cancer, from its likeness to that form of disease in the breast, and is mentioned by Butlin, also by Lagoutte and Wright.[2] There was an absence of any history or sign of syphilis, and the anti-syphilitic treatment had failed. It did not appear to be feasible to attempt removal in this patient, so that it was proposed to continue the present administration of iodide of potassium and opium. As to the pathology of the case, Mr. Spencer said that it had not been examined microscopically, but it did not seem to be a case of fibroid epithelioma as there was no lesion in connexion with the mouth. It might be a glandular carcinoma commencing from some deep racemose gland-cells under the tongue.—Mr. J. HUTCHINSON, jun., said that he had seen a typical scirrhous carcinoma of the penis and he believed that that had originated from the glandular structure in the fossa navicularis.

Mr. H. L. BARNARD showed two cases of Facial thought that in Mr. Heath's fourth, sixth, and seventh cases, it would have been better if the vessels on the right side had been tied.

---

[2] See Butlin and Spencer, Diseases of the Tongue, pp. 322, 462.

Dr. T. R. H. **BUCKNALL** mentioned the case of a man, aged 47 years, who had had syphilis, in whom there was a tumour below the left sterno-mastoid muscle. The patient had signs of pressure on the trachea and left bronchus, but there were no signs of pressure on the recurrent laryngeal nerve. The left carotid and the subclavian artery in its third part were ligatured. The pulsation became less and the patient was free from symptoms for two months.

Mr. **HEATH**, in reply, said that his rule had been to tie the artery which came off next beyond the aneurysm. He quite agreed that in certain cases it was better to tie the right, rather than the left, carotid.

# MEDICAL SOCIETY OF LONDON.

## *Exhibition of Cases.*

A MEETING of this society was held on Feb. 10th, Dr. W. H. ALLCHIN, the President, being in the chair.

Mr. **EDMUND OWEN** showed a case of Traumatic Rupture of the Prostatic Urethra in a boy, aged seven years, on whom a pile of coffin-lids had fallen on Oct. 21st last. The boy had been admitted into St. Mary's Hospital in a state of grave collapse. He was at once taken into the theatre where the house surgeon treated a compound fracture of each tibia. When the house surgeon saw the boy at night blood was oozing from the urethra and no urine had been passed. He then tried to introduce a catheter, and though this did not enter the bladder it drew off a small quantity of blood-stained urine. There was no swelling in the perineum. The house surgeon took no further steps that night towards relieving the bladder, and when Mr. Owen saw the boy next day he had him at once placed upon the operating table and he tried, unsuccessfully, to pass a catheter. He then opened the urethra in the perineum but failed to hit off the track; so he made an incision between the recti abdominis below the peritoneal reflection, and in doing so discovered a quantity of bloody urine around the base of the distended bladder. He next opened the bladder and let out much urine, and then he passed a large drainage-tube through the floor of the pelvis and out by the perineal incision without investigating further. A week later the house surgeon having occasion to put the boy under an anæsthetic passed his finger through the suprapubic wound and out by the perineum, demonstrating the presence of a laceration in the prostatic urethra. Moreover, he was then able to introduce a No. 7 English silver catheter through the urethra and into the bladder. The wounds gradually closed and the boy now passes all his urine the proper way. There is no indication whatever of the prospect of a traumatic stricture.[1]

Dr. **WILLIAM EWART** showed a case of Senile Anæmia associated with Gouty Rheumatoid Arthritis and Dyspepsia. The patient, a man, aged 68 years, was admitted into hospital with great pallor (without yellowish tinge), debility, and slight anasarca (without albuminuria or valvular disease), anorexia, and flatulency with foul tongue and gums, and an indolent, painless, rheumatoid swelling and stiffening of both wrists and of the mid-phalangeal knuckles and of both knees. This swelling had set in about three weeks previously. No hæmorrhages or any other definite cause could be found for the anæmia. The patient had had syphilis 40 years previously and gonorrhœa 23 years previously. He was laid up 20 years before for a month with gout in the toe, and he had had occasional twinges since. He had always been temperate though not a teetotaler. The blood-count gave 2,800,000 red cells and 60,000 white cells per cubic millimetre, and the amount of hæmoglobin was 60 per cent. On careful physical examination no splenic enlargement or other visceral abnormalities could be detected, nor any glandular swellings or other indications of cancer. The case was regarded as one of senile anæmia and arthritis of toxic (alimentary) origin, with leucocytosis. The etiology of the anæmia and leucocytosis in this instance was obscure. Latent carcinoma might be present, although the general improvement which had taken place under treatment rendered this improbable, and, moreover, the gastritis and rheumatoid arthritis might be regarded as a sufficient pathological burden. The patient's age and gouty bias might explain the slowness of recovery from the anæmia.

Dr. **EWART** also showed a case of Tabes Dorsalis in a man who had been for five years subject to attacks of acute abdominal pain, for which he had from time to time been admitted to the hospital. Other symptoms had recently developed which showed the case to be one of tabes.

Mr. C. B. **KEETLEY** showed a case of Excision of a Tuberculous Hip, in which the wound of excision was carefully lined with Thiersch's grafts. The patient was six and a half years old when her left hip-joint (the acetabulum and the head of the femur) was removed by erasion for tuberculous disease. The tubercle, however, extensively affected the superficial parts, subcutaneous and inter-muscular; therefore three weeks afterwards operation was repeated and the whole wound, including the deep part leading into the cavity left by erasion of the joint, was lined by Thiersch's grafts. All the deep grafts and most of the superficial grafts adhered, and from a fortnight after this second operation what little discharge there was came from the superficial sore. This was further grafted, and had occasionally broken out afresh in small parts which, however, readily healed. The hip-joint itself had given no more trouble. This had never been drained by any artificial tube. The temperature rose above 99 5° F. only twice during her stay in the hospital and was generally at or about normal.

Mr. E. **MUIRHEAD LITTLE** showed two cases of Late Rickets. The first patient was a girl, aged 13½ years, who suffered from knock-knee. She had walked badly since she was four years old, but much deformity was not observed until a year previously to her being admitted to the hospital. She was a healthy-looking girl, but was very small for her age. There were bosses on the forehead and on the parietal bones, some teeth were carious, the chest was well shaped but there were distinct enlargements of the ends of the eighth and ninth ribs on both sides, the spine showed lordosis, and the abdomen was slightly distended and the muscles were somewhat flabby. The liver and spleen were normal to palpation. The lower ends of the ulnæ and radii were enlarged and skiagrams showed cupping of the diaphyses as in infantile rickets. She had knock-knee, the ankles being five and a half inches apart when the knees were in apposition. The tibiæ were not obviously deformed. Macewen's osteotomy was performed on both sides and the legs were straightened and were put in gypsum at once. Later, when this was removed, the ankles could be put in apposition without strain. The second case was that of a youth, aged 17 years, who suffered from knock-knee. His mother stated that no deformity had been noticed until he was five years old. Four or five years ago he was an out-patient at the Evelina Hospital for Sick Children and he wore instruments for some time. He had always been thin, but no particular notice was taken of any muscular wasting. He was a tall, long-legged, thin lad. There was little or no subcutaneous fat on the limbs, so that all bony prominences were much accentuated. There was marked fixed lordosis but no paralysis and no contraction of the hip-joints. The great trochanter on each side was in Nélaton's line; the right lower limb was markedly rotated out and there was genu valgum, the leg forming an angle of 145° with the thigh. The tibia and the fibula were slightly bent in their upper thirds, with the convexity inwards. On the left side the knee was contracted and could not be extended beyond 155°. The inner tuberosities of the tibiæ and the lower epiphyses of the tibiæ and fibulæ were enlarged, especially on the right side. The elbows were contracted and could not be extended below 150°. No tendons were abnormally tight and there were no marks of rickets on the ribs or on the wrists. Skiagrams showed the bones of the lower limb to be unusually pervious to the x rays and the epiphyseal lines at the knees were unusually broad and rather irregular. Macewen's osteotomy was performed on both femurs and the right tibia and the right fibula were divided just below the tuberosity of the former. All the bones were soft and were easily penetrated by the osteotome. The patient left the hospital with the limbs in gypsum on Dec. 28th, 1900. Subsequently he was ordered to wear instruments from the boots to the thighs, with ring catches at the knees, and these he still wears.—Mr. W. G. **SPENCER** said that he thought "osteomalacia of puberty" was a better name to apply to the condition present in the first case than the name "late rickets."—Dr. **EDMUND CAUTLEY** said that the

W Byers (Belfast), Dr Edward Malins (Birmingham), Dr John Phillips, and Dr Herbert R Spencer. Treasurer: Dr Francis Henry Champneys. Chairman of the Board for the Examination of Midwives: Dr W R. Dakin. Honorary secretaries: Dr Amand Routh and Dr Montagu Handfield Jones. Honorary librarian: Dr Robert Boxall. Other Members of Council: Dr Comyns Berkeley, Dr Henry Briggs (Liverpool), Dr Thomas Vincent Dickinson, Dr Charles Owen Fowler, Mr Charles Arthur Goullet, Dr Walter Spencer Anderson Griffith, Dr David Berry Hart (Edinburgh), Dr Arthur Corrie Keep, Dr Arthur H N Lewers, Dr Thomas Robert Lombe (Torquay), Dr William Rivers Pollock, Dr Harry Campbell Pope, Mr Edward Reynolds Ray, Dr William Loudon Reid (Glasgow), Dr William Japp Sinclair (Manchester), Dr Thomas George Stevens, Dr Francis T Tayler, and Mr John William Taylor (Birmingham).

## OPHTHALMOLOGICAL SOCIETY

*Intracranial Thrombosis as a Cause of Double Optic Neuritis in Chlorosis.—The Treatment of Cystoid Cicatrix following Cataract Extraction.—Endothelioma of the Orbit.—Ringworm of the Eyelid.—The Visual Purple of the Retina.—Exhibition of Cases and Specimens.*

AN ordinary meeting of this society was held on Jan. 30th, Dr DAVID LITTLE, the President, being in the chair.

Dr C O HAWTHORNE read a paper in which he adduced arguments in favour of regarding intracranial thrombosis as a cause of double optic neuritis in cases of chlorosis.—Sir W GOWERS recalled the fact that he was the first to point out the association of optic neuritis with chlorosis but in such cases there were no true cerebral symptoms, if such a general one as headache was excluded. He doubted the possibility of thrombosis existing without cerebral symptoms, involving at least the sixth nerve. Thrombosis might cause optic neuritis and chlorosis might do so likewise, but to aver that the latter caused optic neuritis by thrombosis was a very wide statement. That chronic bone disease caused optic neuritis was an unquestionable fact, but a great mystery. In such cases there was often no evidence of sinus thrombosis. Middle ear disease might also cause optic neuritis, but not necessarily by inducing thrombosis. Was it possible that disease of the spinal cord and ear disease brought about optic neuritis in the same way? Cerebral tumour often caused optic neuritis, but post mortem there was no thrombosis. Thrombosis might behave like tumour when there was septic contamination with infective tendency. Embolism was associated with septic endocarditis, never with simple thrombosis in an artery.—Dr JOHNSON TAYLOR asked how cavernous sinus thrombosis could exist without proptosis, and why it should affect both sides. The good effects of iron and aperients in chlorosis supported the belief that the optic neuritis was due to some blood change. Mr ERNEST JONES read notes of a case in which thrombosis in the right leg occurred with double optic neuritis.—Dr HAWTHORNE, in reply, said that some chlorotic patients died who suffered from optic neuritis and in these there was nothing but thrombosis present to account for it. He thought that the obstruction need not necessarily be in the cavernous sinus but if it were he should expect proptosis.

Mr G A BERRY read a note on the Treatment of Cystoid Cicatrix following Cataract Extraction. He said that it was not always possible to prevent the formation of cystoid cicatrices after removal of cataract, and when they did occur they were a source of danger to the eye on account of the way in which they facilitated the entrance of micro-organisms. Mr Berry had found that this occurred in about 2 to 3 per cent. of cases operated upon. As a rule the opening was very small and could be seen readily if the conjunctiva were dissected up. For the treatment he preferred to dissect up the conjunctiva and to turn it down as a flap, then with the cautery to burn gently the small opening and at once replace the conjunctival flap. This always cured the defect and he preferred this method to any other that had been introduced.

Mr SIMEON SNELL (Sheffield) related a case of Endothelioma of the Orbit occurring in a girl, aged 19 years, associated with a peculiar varicose condition of the vessels of the surface of the eyeball. A marked feature was the varicose condition of the veins on the surface of the eyeball below, which had been first noticed about three months before the date of operation. There was also marked proptosis, the left eye being about a quarter of an inch in advance of the right. There was no œdema of the eyelids. The smooth surface of the tumour was felt in the floor of the orbit. Movements of the eyeball were normal except downwards, where there was some limitation. Vision was $\frac{6}{9}$. On Oct. 28th, 1901, the entire tumour was removed through an incision in the lower lid without interfering with the eyeball. It had only loose attachments; it reached to the back of the orbit close to the under surface of the eyeball and along the front of the optic nerve. It was encapsuled and measured one and a quarter inches long and about half an inch thick. The eyeball had since resumed its normal appearance and the varicose condition of the vessels had disappeared and vision was $\frac{6}{6}$. Mr Treacher Collins examined the growth for Mr Snell and reported it to be an endothelioma.

Mr SNELL also related a case of Ringworm of the Eyelid in an adult due to a large spored trichophyton, probably of animal origin, occurring in a healthy agriculturist, aged 34 years. The patient was first seen on Dec. 17th, 1901, with a large red patch on the right eyelid which had commenced two weeks before as a rounded, brownish red pimple on the skin near the outer canthus. It gradually increased in size and now measured two inches by one and a quarter inches. It was oval in shape with pustular points and well defined edges. It involved the outer half of the upper eyelid, reached to the temple, and embraced the outer commissure and the outer corner of the lower eyelid. The affected eyelashes and hairs of the eyebrow had fallen out or were loose. The pre auricular gland and the gland beneath the jaw were involved. There were six other lesions on the right forearm and two on the left. In all the patches there was marked loss of hairs. The patient kept cows and one had on the left side a white patch without any hair on it for about two months. The ringworm apparently commenced on the right arm and the eyelid became affected by contact, the man working with his bare arms. Under the application of yellow mercurial oxide ointment improvement soon commenced and on Jan. 30th the patches on the arms had practically disappeared and the one on the eyelid was only distinguishable by its greater redness. Under the microscope a large spored fungus was found, probably megalosporon ectothrix. Cultures from the hairs removed from the cow were not successful.

Dr F W EDRIDGE GREEN read a paper entitled, "Observations on the Visual Purple of the Retina." The expenses of the research were defrayed by a Government grant of £10. He undertook the investigation in order to ascertain whether he could obtain any objective evidence of the diffusion of the visual purple into the yellow spot of the retina. Many phenomena pointed to this conclusion, such as the fact that a perceptible interval elapsed before they were able to see with the yellow spot, and that a light might fall on the fovea without producing any sensation. His first experiments were made with the help of Mr Treacher Collins. On examining the retina of a monkey it was at once evident that the visual purple extended to the yellow spot, but the very deep yellow of the spot prevented them from saying with certainty that the colour altered on exposure to light. Mr Treacher Collins and he had tried numerous chemicals in order to find out a substance which would fix the visual purple but they had not been successful. Nearly every chemical which he had used destroyed the purple. He then examined the eyes of two monkeys by himself and tried to obtain a first view of the yellow spot of the retina through a microscope. It was at first red and then it gradually bleached under the influence of light. He noticed a curious appearance in one retina: on examining the region just external to the yellow spot he saw rose coloured cones surrounded by one or more circles of colourless rods. His last observations were made with the help of Mr Devereux Marshall. Two monkeys were kept in a dark room for 24 hours, and then Mr Marshall excised their eyes under chloroform, the room being illuminated only by a ruby light. The retina having been arranged on a slide was put on the stage of a microscope and viewed with a white light. The whole retina was bright crimson but the brightest part of all was the yellow spot, and it could be seen that the visual purple was situated between, and not in, the cones in the rod free district of the yellow spot. The visual purple in a few minutes bleached, leaving the yellow spot in its usual yellow colour. Dr. Edridge Green

Palsy in Children, one secondary to ear disease and the other associated with hemiplegia of the opposite side of the body coming on after a fall.

---

## OBSTETRICAL SOCIETY OF LONDON.

*Exhibition of Specimens.—Tubal Gestation.—Various Reports.—Annual Address.—Alteration of By-laws.*

The annual meeting of this society was held on Feb. 5th, Dr. **Peter Horrocks**, the President, being in the chair.

Dr. **Amand Routh** showed a Dermoid Cyst of the Ovary of the size of a large cocoa-nut removed per vaginam from a patient, aged 53 years. He asked the Fellows to state their experience as to the best method of treating the vaginal incision after the pedicle had been ligatured and returned. He usually partly closed the vaginal incision and inserted a gauze drain, but sometimes closed it completely.—The **President** said that it might be questioned whether posterior colpotomy was as good as abdominal section for the removal of tumours in general and dermoids in particular. It was true that it might be an easy matter to remove a dermoid through the vaginal roof, but one could never tell beforehand, and if the abdomen had to be opened to complete the operation after the cyst had been opened from below there would be increased risk of soiling the peritoneum with the dermoid contents; and it had struck him that the contents of a dermoid were occasionally more virulent than the contents of ordinary ovarian tumours. Bacteriological investigations, however, had not resulted in the discovery of any specific or specially pathogenic microbe. He preferred after a posterior colpotomy not to close the opening but to drain with sterilised gauze. If the opening were very large it might be partially closed by a stitch or better still by forceps.—Dr. **Champneys** thought that the treatment of the vaginal wound should depend upon its size. If large it should be partially closed and a gauze drain put through the remainder; if small no suture was necessary. He now treated the pedicle of cysts, removed by colpotomy, by pressure forceps and gauze drainage, without ligature, and found the result very satisfactory, the forceps (left on for from 30 to 48 hours) assisting drainage.—Dr. G. E. **Herman** said the special danger attending the fouling of the peritoneum with the contents of dermoid cysts was due to the proneness of dermoids to suppuration, apart from which the contents were but slightly irritant. He thought that after removal of such a cyst per vaginam drainage was not needed, unless suppuration had occurred, or the cyst-contents were known to have fouled the peritoneum.—Dr. **Routh**, in reply, said that he preferred not to use a clamp for the pedicle, but to draw the cyst outside the vulva, retroverting the uterus during that procedure, and then to ligature the pedicle at leisure, all tension of the tissues being thus easily avoided.

Dr. **Routh** also showed a Uterus with Fibroids removed at eight and a half months of gestation by abdominal hysterectomy after Cæsarean section. There were six fibroids, two of which were originally in the pelvis. One was pushed up, but the second one remained in the sacral hollow, preventing all chance of normal delivery. At the operation on Jan. 31st last the obstructing fibroid was found to be firmly adherent to the pelvic floor. Both mother and child remain well.—After Dr. **Herman** and the **President** had spoken Dr. **Champneys** said that the position of the fibroid behind the cervix would have rendered birth *per vias naturales* very difficult, even after destroying the child. He therefore thought Dr. Routh's treatment correct.

Mr. J. **Bland-Sutton** read notes of two cases of Tubal Gestation. The first was that of a woman whose husband, a medical man, had diagnosed a tubal pregnancy, which Mr. Bland-Sutton, after confirming the diagnosis, removed before rupture. The gravid tube was larger than usual owing to the size of the contained blood mole and to the unusual size of the amniotic cavity, which contained a misshapen embryo. The second case had been actually diagnosed by the patient herself and reminded Mr. Bland-Sutton of an artisan's wife whose husband had also diagnosed extra-uterine pregnancy after reading his "Diseases of the Ovaries and Fallopian Tubes." The patient, aged 36 years, had been confined in 1891 and was regular till July 5th, 1901, when a period was missed and the patient suspected extra-uterine pregnancy. Severe abdominal pain followed two cycle rides and Mr. Bland-Sutton was called into consultation. He confirmed the diagnosis and on July 19th removed the left tube and ovary and several ounces of fluid blood in the pelvis. The ampulla of the tube contained a clot as large as a walnut, the cœlomic ostium was large enough to admit a goose quill, and blood leaked freely from the opening during the operation. The walls of the tube were extremely thin but had not ruptured. Typical villi were found at the placental site.—The **President** thought that the explanation of the first specimen being so large without causing rupture was due to the fact that the embryo had perished early, and there had been slow hæmorrhage with formation of partially organised clot. With regard to the second specimen he called attention to the ease with which a tubal gestation might be ruptured during examination or during straining by the patient, and gave details of an unsuspected case that had proved fatal in this way.—Dr. **Herman** pointed out that the clot in Mr. Bland-Sutton's first specimen of tubal mole was in different degrees of decolourisation, indicating hæmorrhage at different dates. Had the patient had successive attacks of pain? He had seen rapid increase of size in tubal moles between examination and operation. He thought the thick layers of fibrin lining the tube would tend to prevent rupture, but the patient would be in danger of hæmorrhage from the open end, and for this and other reasons operation was advisable.—Dr. **Cuthbert H. J. Lockyer** asked if Mr. Bland-Sutton could explain the unusually large size of the amniotic cavity in the first specimen, and Dr. **Routh** asked why the amniotic cavity in tubal moles should be so much smaller than in uterine moles of the same date. He also asked if any Fellow had heard of a "hydatidiform" mole of the Fallopian tubes.—Mr. **Bland-Sutton**, in reply, said he had never seen a hydatidiform tubal mole but felt sure that one would come to hand. He emphasised the President's remarks and always discountenanced dressers examining cases of suspected tubal gestation for fear of rupture of the tube. He endorsed the fact that the amniotic cavity was much larger in uterine moles than in tubal moles, but could not explain it.

On the motion of Dr. **Walter Rigden**, seconded by Dr. H. **Russell Andrews**, the report of the treasurer, Dr. Champneys, was received and adopted.

The report of the honorary librarian, Dr. M. Handfield-Jones, was received and its adoption was moved by Dr. G. F. **Blacker**, seconded by Mr. C. A. **Goullet**, and carried.

The report of the chairman of the Board for the Examination of Midwives was adopted on the motion of Dr. **Thomas G. Stevens**, seconded by Dr. **Lockyer**.

The **President** then delivered the Annual Address. He stated that, including 14 honorary Fellows, there were 654 Fellows, and these included every obstetric physician and every teacher of obstetrics and gynæcology from the medical schools of London. The papers read and specimens shown during the past year had maintained the high standard of former years. Of seven papers read six were obstetric and one gynæcological; but of the 50 specimens shown (excluding new instruments) 34 were gynæcological and only 16 obstetric. The papers and specimens were then reviewed. Obituary notices of six Fellows who had died during the year 1901 were read—namely, Dr. Eugene Goddard, Dr. Thomas Tinley, Dr. John D. Williams, Dr. A. E. Aust Lawrence, Dr. Henry Sutherland, and Surgeon-General Robert Harvey, C.B., LL.D.—On the motion of Dr. W. S. **Playfair**, seconded by Dr. **Herman**, a vote of thanks to the President for his address was passed by acclamation.

Dr. **John H. Galton** proposed, and Dr. G. H. **Drummond Robinson** seconded, a vote of thanks to the retiring Vice-President, Dr. W. R. Dakin, and to the other retiring members of council.

Dr. **Champneys** moved, and Dr. W. H. **Tate** seconded, a vote of thanks to the retiring honorary secretary, Dr. Herbert R. Spencer, and to the honorary librarian, Dr. M. Handfield-Jones, and Dr. **Spencer** briefly replied.

Dr. **Galton** proposed, and Dr. **Playfair** seconded, that the by-law which declared that "registrable medical men" were eligible for election to the Fellowship should be changed, as suggested by the council, to "registrable medical practitioners."—The proposal was carried unanimously.—A law was also passed by which Fellows who might make communications to the society would be permitted to publish their papers in scientific journals after being read.

The following gentlemen were declared elected to serve on the council of the society for the session 1902–1903: President: Dr. Peter Horrocks. Vice-Presidents: Dr. John gastric ulcer had been sent into the cancer ward of Middlesex Hospital by competent practitioners as sufferers from inoperable cancer to linger there and to die, but had gone out cured In the treatment of inoperable cancer pain, hæmorrhage, and the foul fœtor of the discharges were the leading symptoms which had to be treated Morphia relieved the pain and so prolonged life in one way, but it caused loss of appetite and the skeleton like frame which made the patients a terror to themselves and an appalling spectacle to others For nausea or vomiting he had found that the most effective drugs were oxalate of cerium and cocaine given in one grain pills once or twice a day half an hour before food For the fœtor of discharges in addition to frequent irrigation he used an ointment containing vaseline, eucalyptol, and iodoform In some cases of cancer of the peritoneum, especially of secondary disease it was remarkable how long the patients lived and how well they remained in general health, requiring, in fact little treatment of any kind beyond frequent paracentesis abdominis He had not found that patients would consent to undergo oophorectomy when the empirical nature and uncertain effect of the operation were properly explained to them, he knew of no permanent benefit having been effected by it either with the administration of thyroid extract or without In his experience thyroid extract for carcinoma of the breast had not been productive of any good In no case which he had seen had the healing produced by the x rays been sound and permanent The cases recorded as "recovering" or "under process of cure' had been, he considered, published prematurely He thought that all of them would be found to retrogress either during the continuance of the treatment or soon after its discontinuance The x rays produced the same kind of effects by a totally different process that Chian turpentine did in some cases Mr Morris concluded his paper by giving a list of cases of inoperable cancer which had been treated in the wards of the Middlesex Hospital by thyroid extract, by oophorectomy and thyroid extract, by oophorectomy without thyroid extract, and by the Roentgen rays

Mr C Ryall thought that a great deal too much importance was placed on the treatment by oöphorectomy His own experience was that by simple abdominal section in carcinoma of the abdomen considerable shrinking of the growth occurred and the inevitable was postponed

Dr Herbert Snow said that they knew that true sarcoma of the mamma did not affect the lymph glands. It could not be doubted that particles of sarcoma and cells were carried there, and a case of his own showed that the glands in the axilla were in active hyperæmia in such a case, but infection did not occur Judging from the course of epithelioma on the wrist or on the foot he formulated the principle that the nuclear cells or infective particles of carcinoma must be destroyed either in the lymph current in these cases on their passage to the gland, or by the cells in the glands, or by some secretion in the glands He had appealed in the columns of THE LANCET for some laboratory to take the matter up, but that was not responded to In that direction only was there any question of real treatment worth the name for inoperable cancer

Mr C R B Keetley said that everyone who accepted the hypothesis that cancer was probably due to some germ must realise that every case of cancer attended by discharge was a possible focus for spreading the disease.

Dr F H Low showed the apparatus used in the production of high frequency currents and the methods of their employment therapeutically Locally applied a large number of skin diseases were being treated in this way and with very promising results The general effect obtained was one of increased nutrition resulting in marked improvement in general health and tone

---

# EDINBURGH MEDICO-CHIRURGICAL SOCIETY

*Exhibition of Patients Specimens, and Apparatus — Chloroma*

THE fifth ordinary meeting of the present session of this society was held on Feb 5th, Professor T R Fraser, the President, being in the chair

Dr William Stewart showed a man who had suffered a Compound Dislocation of the Ankle, with Fracture of the Neck of the Astragalus and Removal of the Outer Malleolus (with stereoscopic photograph)

Mr Francis Caird showed a man, aged 61 years, who had suffered from Chronic Obstruction for two years, the bowels only acting once in two or three weeks The abdomen was very greatly distended and splashing and gurgling were loud The diagnosis was a carcinoma of the ileo cæcal valve. At the operation a bobbin shaped stricture of the ileum was found with involvement of the mesenteric glands. To get clear of the disease 70 inches of gut were removed at the first operation and later the cæcum and a piece of the colon were removed (in all 80 inches) and the two ends were sutured It was found that the infiltration was solely tuberculous The patient had improved daily since the operation

Dr Dawson F D Turner showed 1 A young woman who had suffered from Lupus Vulgaris The disease improved very slowly under treatment by Roentgen rays On Jan 13th ultra violet light treatment was begun thrice weekly with two and a half minute applications and at once great improvement was manifest The patient had had in all seven exposures and she was practically cured 2 A man who had suffered from Rodent Ulcer on the right side of the nose for eight years It was of the size of a small mussel shell and was covered by crusts The ulcer was one eighth of an inch deep On Dec 4th, 1901 x ray treatment was commenced and the patient slowly improved On Jan 10th, 1902 ultra violet light treatment was begun thrice weekly and after only three exposures the patient was almost cured

Dr Turner also exhibited an Apparatus for Generating Ultra violet Light Acting on a suggestion of Mr Leslie Miller he had been comparing the ultra violet radiation of a Tesla spark gap with that of an arc light His apparatus resembled that which had been in use by Dr Hugh Walsham of London and Dr Gorl of Nuremburg, and it consisted essentially of an induction coil, a condenser, and a spark gap of two or three electrodes The ultra-violet radiation of this spark, as tested in his laboratory, was altogether of a higher order than was that of an arc lamp, while the heat radiation was almost negligible Owing to this latter property the light could be brought within an inch or within two inches of the skin with very greatly increased effect After a number of experiments as to relative transparency and convenience Dr Turner preferred to use pure rock salt as a compressing agent The clinical results obtained had been remarkable an exposure of only two and a half minutes being amply sufficient to produce a marked beneficial effect

Cases were also exhibited by Mr Caird and Mr Purves, and card specimens by Dr A Logan Turner, Professor T Annandale Dr Gibson, and Dr S McDonald

Dr G H Melville Dunlop then read a paper upon a case of Chloroma exhibiting microscopical sections and photographs He stated that at the November meeting he had exhibited a little boy suffering from chloroma The child died a fortnight later and he proposed to give a record of the case together with an account of the post-mortem examination and some brief notes on this rare and interesting disease The boy, aged five years, was admitted to Dr Dunlop's ward in the Edinburgh Royal Hospital for Children on Sept 30th, 1901, complaining of great weakness and swelling of the face The family history was unimportant. The father had suffered from an attack of rheumatic fever and the mother from repeated attacks of bloodlessness Two children had died during infancy There was no family history of tubercle or of renal disease As to the previous history it was elicited that the child was born at full term and was a healthy baby He had had whooping cough when he was six months old, measles when he was three years of age and he had had frequent attacks of bronchitis but was, on the whole a healthy child With regard to the present illness it was ascertained that for fully a year patches of ecchymoses were frequently noticed under the skin and were attributed to bruises In May, 1901, the extreme pallor of the face of the patient was first noticed, and for some months previously it had been observed that any scratch which he received appeared to suppurate immediately At the beginning of June a boy dipped him into a horse trough He remained in his wet clothes for some hours The chill which he received kept him in bed for some days with fever and headache The child was never the same after this and he seemed to get more easily tired He commenced to call out in his sleep and to snore at night His appetite became very poor and the pallor and emaciation steadily increased At the beginning of August he became dull and languid and ceased to play or to go out of doors On August expressed his great indebtedness to Mr. Collins and to Mr. Marshall, and also to Professor E. H. Starling for the use of his laboratory and the very admirable dark room at University College.

The following cases and card specimens were shown:—

Mr. **George Keeling**: Unusual Refractive Change after Removal of a Congenitally Dislocated Lens.

Dr. **H. R. Belcher Hickman**: A case of Retinitis Proliferans.

Mr. **G. W. Roll**: A Congenital Anomaly of the Optic Disc.

Mr. **A. W. Ormond**: A case of Double Anophthalmos.

Mr. **J. H. Parsons**: Microscopical Sections of Pseudoglioma due to a Congenital Membrane.

Mr. **Inglis Taylor**: Fenestrated Metallic Balls used by Professor Pflüger in Mules's operation.

Mr. **Holmes Spicer**: A case of Third Nerve Paresis with Argyll-Robertson Pupil and Marked Association of Convergence and Contraction of the Pupil

Mr. **R. Marcus Gunn**: Unusual Deposit on the Inner Surface of Each Cornea of Recent Origin and Slow Development.

## HARVEIAN SOCIETY OF LONDON.

*Scleroderma and Raynaud's Disease.—Epistaxis and Rheumatism.*

A MEETING of this society was held on Feb. 6th, Mr. **W. Watson Cheyne** being in the chair.

Dr. **William Ewart** read the clinical history of a case of Scleroderma associated with Raynaud's Disease, making special reference to treatment. The patient was a woman, aged 30 years, who had been under observation since November, 1900, and had then suffered for five years from mild symptoms of Raynaud's disease and from aggravated dyspepsia and gastric and cardiac attacks. These latter symptoms had been much more severe during the last six months, when she became aware of the tightening of the skin of the hands and feet and of the face, slightly also of the shoulders. Dr. Lee Dickinson, who had treated her at the end of 1900, had then observed the early beginnings of scleroderma, and the first alteration in facial contour and expression had been noticed by the husband four years ago. Since her admission to St. George's Hospital on Jan. 2nd, 1902, she had made considerable progress. The face had lost much of the pinched aspect and was smooth and oval. The lips were again supple for articulation, smiling, whistling, &c., the fingers and wrists had ceased to be rigid and, indeed, were freely moveable, and she could once more stoop to the ground so as to reach her feet. The treatment had been chiefly hygienic for the visceral, and thermo-mechanical for the cutaneous, trouble. She had been kept at rest in bed and had been fed on light food which had been well digested, on port wine, and on olive oil and whisky. The hands had been kept oiled and gloved and perpetually in contact with a hot-water bottle inside of a bag of cotton-wool, except for the periods of passive movement, of massage, and of skin massage. The recurring local asphyxia of the fingers had in this way been quickly remedied and pliability of the skin had been restored to a great extent, whilst the gastric and cardiac symptoms had remained in abeyance. The medicinal treatment had been diaphoretic and vaso-relaxant, the medicines administered having been liquor trinitrini (nitro-glycerine), spirit of nitrous ether, acetate of ammonia, and an occasional mercurial pill. After a few days she was allowed to get up for part of the day and to take exercise. In her case the scleroderma had preceded the Raynaud's disease by several years, as shown by the history of the minute scars on all the finger tips Emaciation had been marked and the thyroid was small.—Dr **Alexander Morison**, Dr. **Barton**, and Dr. **G. A. Sutherland** took part in the discussion.

Dr. **Sidney P. Phillips** read a short paper on Rheumatism as a cause of Epistaxis in Children. (We hope to publish this paper in an early number of THE LANCET.)—Dr **Ewart** said that the great frequency of epistaxis in childhood which must be due to definite causes hitherto imperfectly explained must lead to its being not uncommon in children suffering from rheumatism, particularly as in this disease there was a well-marked tendency to hæmolysis. The mechanical factor of local congestion, as in tonsillitis, might also have a great share in this result.—Dr. **Leonard G. Guthrie** said that in his experience epistaxis was more frequently associated with migraine than with rheumatism in children.—Dr. **Morison**, Dr. **Travers R. M. Smith**, Dr. **E. Cautley**, Dr. **C. S. Jaffe**, Dr. **H. J. Macevoy**, and Dr. **Sutherland** also took part in the discussion.

## WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

*Discussion on Inoperable Cancer.*

A MEETING of this society was held on Feb. 7th, Mr. **Alfred Cooper**, the President, being in the chair.

Mr. **W. McAdam Eccles**, in opening the discussion, said that the cases which interested most of them, if not all of them, were those cases of recurrent carcinoma after operations upon the mammary gland. He thought that surgeons and medical men generally should study any means that there might be for the treatment of these cases. There had come up of recent years an operation quite away from the local field of the original growth that generally went by the name of "Dr. Beatson's operation," consisting of removing both ovaries. He considered that the operation was perhaps one which was justifiable under certain circumstances, not only from the possible good that might accrue to the patient, but also from the knowledge that might be gathered. In spite of the fact that no good had followed in a considerable number of the cases the operation, in his opinion, was justifiable provided the patient clearly understood its nature—namely, that it was the removal of both ovaries and that it was distinctly an experiment so far as her individual case was concerned, and provided further that the patient and her friends desired that it should be undertaken. Surely, the very fact that a certain proportion of cases had been benefited made the procedure right even if they could not hope for a complete cure. Although they did not know what were the exact points for and against the operation he thought that it was a subject which they ought to consider further and to investigate, because there seemed to be something in it which they did not quite fully understand

Mr. **Stanley Boyd** said that the results of a successful oöphorectomy were: (1) the relief of pain; (2) the vascularity of the nodules became reduced and the nodules shrank and disappeared in the course of a few weeks or months; (3) secondary nodules in the opposite breast receded more slowly; and (4) strength and weight were gained, the patient's spirits rose, food was taken better, and life presented itself to the patient in a different aspect. The question asked by a patient was, Supposing the cancer disappeared how long would it remain away? In order to answer that it was necessary to consider the indications which pointed to the most likely cases for affording the best results. 1. It was only in cancer of the breast that the operation, so far as they knew, was of any influence at all. 2 The amount of disease present provided it was local was not a contra-indication to operation. 3. Cancers of slow growth had yielded more favourable results than cases of acute cancer. 4. A larger number of good results seemed to have been obtained in patients after 40 years of age than before that age. 5. Obvious lesions of the viscera and bones had never been known to disappear after the removal of both ovaries, but it was possible, of course, that unrecognised nodules which were small had disappeared. They did not know, but it might be that the growth of some of those visceral troubles had been controlled or retarded by the oophorectomy. 6. Complete establishment of the menopause had not been shown to be a contra-indication to the operation. There was very little experience on the subject. He had performed the operation in one case on a woman, 64 years of age, the cancer having been, so far as he could judge, a rapid one up to the time of the oöphorectomy, but it changed its character afterwards and he considered that it was retarded in its growth. With regard to the thyroid treatment he had not seen any good result from it. In his opinion they would get something good out of the x rays, and he had no doubt that the burning would be avoided in the future.

Mr. **Henry Morris** communicated a paper in which he described how patients suffering from syphilitic ulceration, chronic inflammation, polypus of the rectum, and cicatrised tumours originated from the periosteum of the head and face, and they grew secondarily in other organs. Nearly every organ had been invaded by secondary growths in the cases recorded with the exception of the nervous system. The brain might be compressed by, but it was never invaded by, the tumour growth. Of the internal organs the kidneys were most affected, but in only one other case besides the present one was the muscular substance of the heart invaded. The bones were frequently so distended by the growths as to become translucent. Erosion or pitting of the bone was a marked feature in many of the cases. The consistence of the tumours varied from that of a soft gelatinous mass to a hard and gelatinous consistence. The cut surface was homogeneous, with or without fibrous septa, and no trace of blood-vessels was to be seen. Microscopically the tumours consisted of large round or oval-shaped cells slightly larger than a white blood corpuscle, containing many nuclei and nucleoli occasionally. These cells were either embedded in an inter-cellular amorphous material of a very clear and transparent character or in a delicate network. At other times the tumour was interspersed by coarse bundles of connective tissue. In the midst of this network the granules, with the highly refractile properties referred to, were found lying in and between the cells. Chloroma was chiefly a disease of children and adolescents, and boys seemed to be attacked to a greater extent than girls. With regard to the relationship of this condition to leukæmia Recklinghausen first noted it. Dock pointed out a further resemblance in the similarity of the symptoms. Thus deafness was common to both; in chloroma it was due to the pressure of tumours in the internal, middle, and external ears. In leukæmia, though sometimes ascribed to hæmorrhage, in many cases it was caused by the pressure of leukæmic tissue in the ear. Exophthalmos was common to both diseases, while progressive anæmia of a marked character—accompanied by petechial extravasations, epistaxis, and subconjunctival and retinal hæmorrhages—was found in both. So far as Dr. Dunlop had been able to gather the case which he described was the first in which a diagnosis of the condition was made during life. Before the appearance of the tumours a diagnosis would be impossible as the symptoms would be only those pointing to leukæmia. When subsequently to those symptoms exophthalmos, failing sight, deafness, and tumours in the temporal regions and in other parts of the body supervened the diagnosis of chloroma should always suggest itself. The prognosis was invariably fatal from exhaustion, the average duration being five or six months, although cases had been recorded lasting above two years.

Dr. **BYROM BRAMWELL** then read full notes of a case of Chloroma, and also of a case of Lymphatic Leukæmia. An account of these cases will be given in our next issue.

*(To be continued.)*

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF MEDICINE.

*Scarlet Fever.—Traumatic Functional Paralysis.*

A MEETING of this section was held on Jan. 24th, Dr **J. HAWTREY BENSON**, being in the chair.

Dr. **J. M. DAY** read a paper on the Diagnosis of Scarlet Fever. This, he said, had now become a far more difficult matter than formerly when the disease was of a severer and better marked type. The chief symptoms of scarlet fever were vomiting, sore throat, elevation of temperature, frequent pulse, and a rash. If scarlet fever was present the red punctiform appearance on the pharynx, soft palate, tonsils, and hard palate would be found. The pulse-rate was quick, even in the mildest cases. The rash was never seen in the circum-oral zone. The skin was dry, but sweating might occur in rheumatic subjects. When the disease was accompanied by gastric catarrh the tongue was furred. Scarlet fever might occur a second time without eruption. Desquamation might commence on the sixth day, or might be delayed until the twenty-first day. It spread centrifugally from points. Scarlet fever might be confounded with rötheln, measles, septicæmia, urticaria, erythema, rheumatic fever, meningitis, enteric fever, and drug-rashes.—Dr. **HAYES** said that he had found the difficulty of diagnosis of scarlet fever most in adults. In mild cases there was no constitutional disturbance and the typical scarlet fever throat might be absent. He based his diagnosis principally on the punctiform rash of the hard and soft palate and the rapid pulse. Temperature was of little diagnostic value and desquamation was not easy of recognition in every case.—Dr. **HEAD** said that he thought that desquamation might be deferred for a longer period than 21 days. He spoke of a series of cases in which desquamation was deferred for a month. In the "fourth disease"[1] the skin peeled in large patches.—Dr. **H. C. DRURY**, Dr. **J F. POLLOCK**, and others also discussed the paper.—Dr. **DAY**, in his reply, said that he did not know any surgical scarlet fever. There might be septicæmia with a rash or a surgical patient might contract scarlet fever. The period of incubation, he thought, was generally known—it was eight days. The infection was not so much due to the desquamation as was formerly thought. Any discharge, such as otorrhœa, might convey infection. He looked on the "fourth disease" as non-existent, being no more than a form of rötheln.

Dr. **MARTIN DEMPSEY** brought forward a case of Traumatic Functional Paralysis—a boy, aged about 12 years, who had fallen from a height a considerable distance on his right shoulder-joint. He did not appear to suffer much from the fall at the time. The joint was examined by means of the x rays and was rubbed with an anodyne liniment for weeks, but without benefit. The right arm hung helplessly by his side, with the fingers slightly flexed at their terminal joints. At the slightest touch the boy now complained of excruciating agony in the injured limb as low down as the elbow-joint; he could not recognise hot water in a test tube and yet had no difficulty in recognising the presence of cold water. All the muscles reacted to the faradic current. For two months the current was applied with distinct benefit, the boy regaining some of the power of the limb. He was now able to flex it and had a considerable grasping power in his hands. Dr. Dempsey looked upon the case as one of functional or hysterical paralysis, and his prognosis was favourable.—Dr. **CRAIG** agreed with Dr. Dempsey in his diagnosis. He had had a somewhat similar case in a girl.—Mr. **W. LANGFORD SYMES** said that he had seen many cases of functional diseases in the Great Ormond-street Hospital, London. A diagnosis might usually be made by throwing the patients off their guard. All of the cases were in boys and were associated with phimosis. Dr. Dempsey's patient had a long foreskin.

**LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Jan. 31st, Dr. T. Churton being in the chair.—Mr. A. W. Mayo Robson read a paper on a series of cases of Fractured Semilunar Cartilage of the Knee-joint.—Dr. Churton, Mr. H. Littlewood, Mr. B. G. A. Moynihan, and Mr. R. Lawford Knaggs took part in the discussion, and Mr. Mayo Robson replied.—Dr. W. McGregor Young read a paper on the Advantages of a Bag Pervious to Air in Ether-giving. He said that air-limitation for all practical purposes was a necessity, but the question arose as to whether in using the ether-bag they did not go too far and produce often an undesirable state of anoxyæmia; certainly in unskilled hands this was apt to occur. It seemed to him that the advantages of the semi-open method in vogue in America might be combined with those obtained in using a Clover's regulating apparatus if instead of an air-excluding rubber bag a bag made of some porous fabric was used. Although by no means the only cause of cyanosis, the rubber bag was probably the most common one, and cyanosis was an undesirable and even dangerous condition and the reproach of ether-giving. Besides, the rubber bag was an unclean thing. Dr. Young showed the bag which he proposed as a substitute made of Holland linen. He claimed that with this bag cyanosis was avoided, and as regards cleanliness it was beyond reproach, for a fresh bag newly washed and starched from the laundry was used for each case. He had tried it in a very large number of cases with excellent results. Chloroform could be added to hasten the anæsthesia by simply dropping it on the outside of the bag. He found that the asphyxial factor being absent the corneal and pupillary reflexes were no longer indicative of the same depth of anæsthesia.—In the discussion which followed Mr. Mayo Robson spoke strongly in favour of Dr. Young's

---

[1] THE LANCET, July 14th, 1900, p. 89.

16th the mother noticed that his eyes were prominent and that the veins on the eyelids were dilated. This exophthalmos had gradually increased. Deafness was noticed about the middle of September and this had increased gradually. His teeth had always been bad and he had suffered from toothache since he was three years of age. At the commencement of October the child was treated for an abscess of the scalp and he had an attack of albuminuria accompanied by pyrexia which lasted for a few days. On admission he looked extremely ill; his weight was 39 pounds. His complexion was very pale and of a waxy, yellow tint. He could stand, or sit up, or walk. He was a quiet, placid, good-tempered child. A large number of petechial hæmorrhages, of about the size of, and having the appearance of, flea-bites were scattered over the skin of the whole body with the exception of the face. In addition there were two larger hæmorrhages over the spinal column and over the right knee, as also evidence of an old hæmorrhage on the right shin. The face was pale and pasty, with marked puffiness of the eyelids, especially of the left eyelid. Some œdema and marked anæmia of the conjunctivæ were noted, as well as considerable protrusion of both eyeballs, though the patient could close his eyes. There were a few slightly enlarged glands under the lower jaw on both sides, as also in the posterior triangles of the neck and in the groins. The axillary glands were not enlarged. The thyroid was normal in size, as also was the thymus. The respiratory and circulatory systems were normal, with the exception of a loud hæmic bruit heard on both sides over the vessels of the neck. The digestive system showed nothing abnormal with the exception of a very large number of carious teeth. The urinary system was normal. Hæmoglobin in the blood, 32 per cent.; red blood corpuscles, 1,800,000; and leucocytes, 24·5000. Films showed a large number of lymphocytes, both large and small, the former preponderating and numbering about 73 per cent.; polymorphonuclear, 17 per cent; myelocytes, 5 per cent.; unclassified and transitional forms resembling myelocytes, 5 per cent. A few nucleated red cells were present. On Oct. 15th two fresh hæmorrhages had appeared and the eyeballs were becoming more prominent and the deafness was increasing. A hard, indurated swelling of a purplish colour was found occupying the hard palate on both sides in its whole extent antero-posteriorly, and a similar but smaller swelling was present on the right side of the lower jaw externally to the teeth. By the 22nd a smooth, rounded swelling had appeared in each temporal region extending into the orbit on either side. This was firm but not of a bony hardness, and was attached to the bone below but not to the skin. The diagnosis of chloroma was made at this date. A few days later the upper eyelids became infiltrated with firm, smooth swellings, as also the lower right eyelid. During sleep the eyeballs were only half covered by the lids. The ophthalmoscope revealed a minute hæmorrhage near the disc of the right eye. The retinal veins were tortuous and distended in both eyes. The appearance was like that of optic neuritis. On Nov. 6th a pale, greenish-yellow tumour of a jelly-like consistence appeared at the inner canthus of the right eye and it gradually advanced over the eyeball, covering its lower half. The left eye was affected similarly but to a less extent. The boy complained now of severe pain in the frontal region and photophobia was marked. The temporal tumours appeared to have diminished in size and the optic neuritis had increased in severity and the retinal hæmorrhages in number. By the 12th the growths had covered both eyeballs and the corneæ were apparently quite destroyed. The leucocytes were now 107,000, the red blood corpuscles 815,000, and the hæmoglobin was 12 per cent. The boy died from exhaustion on the 16th. At the necropsy the spongy bone of the manubrium sterni was found to be of a dull greenish-grey colour. The lungs were pale, but they were interspersed with irregular patches of congestion and extravasations. Two small greenish areas were present on the surface of the heart. The ribs were of a green colour in their whole extent, the green being deepest just in front of the angles. The periosteum of the vertebræ from the neck to the pelvis was infiltrated and thickened with greenish tissue, continuous with that passing along the intercostal vessels and nerves. During the progress of the post-mortem examination the green colour gradually faded. Many minute hæmorrhages were present in the gastro-intestinal mucous membrane. The kidneys presented very striking naked-eye appearances, being very pale and of a pinkish-green colour and dotted over with distinct green spots under the capsule. On section numerous bright green areas varying in size from a pin's head to a quarter of an inch in diameter were found. These were chiefly found in the cortical areas near the medulla. The mesenteric glands were merely enlarged, while one or two greenish glands were found near the head of the pancreas and others in the same neighbourhood contained brownish pigment. The pancreas was of a pale, yellowish-pink colour and contained small greenish nodules in its substance. On reflecting the scalp green tissue was found extending along all the sutures, but it was confined to the pericranium and could be stripped completely off the bones. Underneath and infiltrating the substance of the temporal muscles new growths from a quarter to three-eighths of an inch in thickness were present; they were bright grass-green in colour. These had evidently developed from the periosteum and had extended deeply into the spheno-maxillary fissure. The diploë throughout was of a dirty greenish colour and over the dura mater numerous green patches were present. The brain and spinal cord were healthy. All the bones in the anterior part of the skull were infiltrated with dull green material. In the orbits numerous sharply defined masses were present surrounding the optic nerve and eyeballs and extending under the conjunctivæ. The soft palate, the walls of the pharynx, the tonsils, the mouth, and the gums were infiltrated with deposit. Numerous bones which were examined showed the presence of this green material in the medulla. Only 24 cases of chloroma had been recorded. The first case was recorded by Alan Burns in 1823. He regarded it as a condition differing from any morbid affection hitherto described. He thought that the new growth originated in the lacrymal gland. Recently Dock of Michigan and Gustav Lang of Nancy had written exhaustive monographs on the subject. The tumours had been variously described as green cancer, fibro-plastic tumours, amorphous fibrous tumours, and pigmented myxo-sarcoma or chloro-myxo-sarcoma. Huber defined the condition as a metastatic periosteal sarcoma and he maintained that the tumours always originated in the bones of the head and face and that the growths in other organs were secondary and were originated by metastasis. Recklinghausen, in 1883, stated that the tumours in chloroma differed in many respects from periosteal sarcomata and he insisted on the intimate relation between this affection and leukæmia. He showed that the structure of all the tumours in his case was of a pure lymphomatous character, and in this belief he was supported by Höring, Dock, and Chiari, and several other writers, with the result that the growths were generally regarded as belonging to the class of tumours known as lympho-sarcomata. "Lympho-sarcoma" was probably the best definition of the growths found in chloroma—resembling on the one hand lymphoma in their histological structure and sarcoma in the fact that they arose from the periosteum and that they spread by metastasis. Recently the view had been advanced by Cordua and Ricker that a very close relationship existed between lympho-sarcoma and tuberculosis. Regarding the cause of the colour of these tumours, which varied from a yellowish-green to a bright grass-green, considerable diversity of opinion was held. No bile pigment had ever been discovered in any of the tumours. Nor was it due to decomposition, as Dittrich suggested, for the colour was confined to the growths absent from the other tissues, and portions of the tumours removed during life had a green colour. Huber had made an elaborate investigation on fresh tumours to discover the source of the colour. He ascribed it to minute molecular granulations possessing great refractive power placed between the cells. Virchow, Dressler, and Chiari were at one with Huber in considering that the colour proceeded from the adipose granulations found in and between the cells. The colour quickly disappeared from periphery to centre on exposure to air or on immersion of the tumour in water, alcohol, chloroform, or ether. Dock, in giving his adherence to the fatty theory, considered that it was simply an exaggeration of the greenish tint so common in the neoplasms of leukæmia and which he maintained was another proof that these conditions were closely allied. In view of the quick disappearance of the colour on exposure to air and on immersion in fluids that had no solvent action on fats the theory of the fatty granules appeared difficult of acceptance, and Dr. Dunlop thought that the colour was more probably due to some chemical product allied to lipochrome, hitherto undiscovered, which on exposure to light became oxidised and in the process of oxidation lost its colour. It was admitted generally that the to promote expulsion When separation had not taken place within a reasonable time he adopted the plan of inserting the hand into the uterus —Dr J M Munro Kerr dwelt on the importance of giving time for the placenta to detach itself he waited in some cases as long as 30 minutes Separation was known by bulging of the lower part of the uterus *by the tapering of the fundus*, and *by the descent* of the cord, the latter having been tied with tape at the vulva as an indicator He concluded by discussing the theories held regarding the process of separation of the placenta.—Dr E A Gibson dwelt on the necessity of giving time in the management of the third stage When there was undue hurry and when pressure was applied there was risk of severe hæmorrhage He did not recommend the giving of ergot in the third stage of labour —Dr W K Peden insisted on the necessity of giving time in the third stage and criticised adversely the application of pressure to the uterus before the placenta had separated When separation was unduly delayed the best method in his opinion was to insert the hand into the uterus and to ascertain the cause of delay —Dr James Hamilton remarked that his policy was not to delay longer than 15 minutes for separation and expulsion At the close of this period he made traction with his hand in the uterus He did not advocate delay in the management of the third stage of labour —Mr Alexander Miller said that he only used Credé's method when the placenta had separated and was lying in the lower part of the uterus —Dr R. Jardine advocated a delay of 15 minutes in order that the placenta might separate During this interval he steadied with his hand the fundus of the uterus to prevent relaxation and the filling of the cavity of the uterus with blood Separation having taken place and the placenta lying in the vagina his method was to make traction on the cord In cases of adherent placenta he introduced his hand and separated the placenta himself —Dr Malcolm Black said that he never inserted his hand into the uterus unless the circumstances strongly demanded it He used Credé's method only after separation had taken place and the latter was known by the distance travelled by the cord ligatured at the vulva —After some other members had taken part in the proceedings the President concluded the discussion and expressed the opinion that the third stage of labour was the most important of all After separation of the placenta his practice was to use Credé's method, taking great *care that no part of the membranes was left behind*

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM —A meeting of this society was held on Feb 3rd —Dr Urban Pritchard the President delivered a brief address, in which he referred to the interesting and valuable work done in the two sessions already held and he expressed the hope that some of the younger members would strive to find solutions of the difficult problems connected with non suppurative disease of the middle ear —Dr L Hemington Pegler in conjunction with Mr Richard Lake showed a case of Double Subdural Abscess Secondary pyæmic symptoms developed after the operation , the lateral sinus and brain were explored and the patient made a good recovery —Mr P Macleod Yearsley showed a patient upon whom the complete post aural operation had been done without grafting and had been followed with great improvement in the hearing power —Dr J Dundas Grant showed a case of Cerebral Abscess attended with unusual features and in which recovery had followed operation —Mr L A Lawrence showed a Tortoise Shell Instrument consisting of a flat plate made to fit behind the ear and of the same sort of use as the hand placed in a similar position It was invented by an artist who was not in the least acquainted with any medical matter but who found that his own deafness was benefited by using the instrument In some few cases the instrument had certainly improved the hearing —Dr A. L Whitehead made a brief communication on the Use of Adrenalin Chloride in the Mastoid Operation and also read the notes of Two Cases of Aural Disease terminating fatally —Dr W Jobson Horne showed a specimen of the Middle Ear destroyed by Tuberculosis, and also exhibited Microscopical Sections from the Integuments of the Temporal Bone demonstrating the presence of Tubercles and Tubercle Bacilli

ROCHDALE AND DISTRICT MEDICAL SOCIETY —A meeting of this society was held on Feb 6th —Mr W P Montgomery read a paper on the Treatment of Some Common Deformities of the Feet He said that these conditions giving rise to great discomfort, were usually either left to the surgical mechanician or subjected to operation Much, however, might be done in the way of treatment by applying one's knowledge to each case In talipes equino varus up to the age of six months the varus deformity should be corrected by the moulding of the foot by the mother or nurse. The equinus deformity should be left till later Plaster, boots and artificial muscles were useless Between the sixth and eighteenth months of life tenotomy of the tendo Achillis should be done and some form of splint should then be worn at night only and should be continued up to the age of five years The child should also be trained to walk properly In severe and relapsed cases more drastic operative measures would be required—e g tarsectomy Such operations however, left a short and inelastic foot The occurrence of flat foot was favoured by the position of the feet in the walk of civilisation—viz the toes out position Boots also contributed to the production of flat foot by leading to the formation of corns and bunions and consequently of faulty positions of the feet also by inducing weakness of muscles from disuse With a view to the prevention of flat-foot infants should be made to wear either sandals or light shoes not boots Afterwards the boot should be made on anatomical lines with a straight inner side Curative treatment should include rest, preferably in the tailor's sitting position Tiptoe exercises should be practised daily and a mechanical support should be worn Operation might be necessary in a bad case The treatment of Morton's disease and that of deformities of the great toe and of hammer toe were also discussed With regard to deformities due to infantile paralysis, when these became fixed it had been suggested that the transplantation of the tendon of an active muscle to the site of insertion of a paralysed muscle might be of value —Mr Montgomery was awarded a cordial vote of thanks for his paper

ÆSCULAPIAN SOCIETY OF LONDON —A meeting of this society was held on Feb 7th, Dr Arthur T Davies, the President being in the chair —Dr T G Stevens discussed the subject of Displacements of the Uterus in relation to (1) the physical conditions giving rise to them (relaxation of suspensory ligaments increase in the size weight and consistence of the uterus, relaxation or injury of the pelvic floor and increase of intra abdominal pressure) , and (2) their treatment Anteflexion he considered to be usually not a true displacement but a local malformation Retroflexion and retroversion were sometimes congenital, commonly so when occurring in unmarried girls These cases if not associated with congestion leucorrhœa or menorrhagia, were best left alone In married patients retroflexion was usually an effect of ovarian irritation with relaxation of the uterine ligament the uterus falling back into the hollow of the sacrum and being retained there by the pressure of the bowel which passed down in front of it Relief of ovarian trouble was the first consideration This object was best attained by ichthyol suppositories and vaginal douching Replacement (bimanual) should precede the use of a pessary which at best was but a palliative measure Operation alone was curative In this connexion it was best to incise the peritoneum through the anterior fornix and to stitch the fundus uteri to the peritoneum of the utero vesical pouch—vaginal fixation Prolapse was of two kinds—(1) acute, produced by sudden strain and constituting really a hernia of the pelvic floor in which the uterus took part and (2) chronic due to gradual relaxation and subsidence of the peri uterine tissues The former condition was the more tractable and in young girls was often cured by time and dietetic treatment The latter was very intractable Pessaries did little good glycerine plugs with a firm external pad were better Of operative methods Dr Stevens preferred ventral suspension by attachment of the urachus to the abdominal wall In elderly women with great prolapse he advocated hysterectomy with removal of the upper third of the vagina, so as to form a firm supporting fibrous pillar in the vagina —A discussion followed

NORTH EAST LONDON CLINICAL SOCIETY —A meeting of this society was held on Feb 6th, Dr F J Tresilian the President being in the chair The following cases and specimens were shown —Dr A J Whiting A case of Nodding Spasm in an infant with rickets —The President A case of a Testicle for Diagnosis It was considered to be a hæmatocele with thickened walls —Dr S E Dore Some cases of Lupus under method.—Dr. T. W. Griffith and Mr. Michael A. Teale also took part in the discussion, and Dr Young replied.—The following cases, pathological specimens, &c., were shown. Mr. H. J. Roper: A specimen of Amputation through the Forearm for Diseased Wrist-joint in a man, aged 68 years.—Dr. A. Bronner (Bradford): Two cases of Saddle-nose treated by Subcutaneous Injections of Paraffin.—Dr. C. Powell White: Urine from a case of Bilharzia Hæmatobium.—Mr. Littlewood: (1) A child, aged four years, with Volkmann's Contracture, treated by Tendon-lengthening; (2) Renal Calculi; (3) a specimen of Perforating Ulcer of the Upper Part of the Rectum producing General Peritonitis; and (4) a New Instrument—Forceps Dissector.—Dr. Churton: (1) Three patients recovering from Acute Cerebral Endarteritis (Syphilitic) with Aphasia; and (2) a Brain showing Syphilitic Endarteritis.—Mr. Moynihan: (1) A patient operated upon some months ago for supposed Malignant Disease of the Stomach (the tumour, of large size, adherent and irremoveable, had entirely disappeared); and (2) a specimen of Calculous Pyonephrosis.—Dr. Griffith: (1) Two cases of Heart Disease; (2) a case of Progressive Muscular Atrophy; and (3) (with Mr. Moynihan) a specimen of Perforated Gastric Ulcer.—Mr. Mayo Robson: (1) Double Pyosalpinx (tuberculosis); (2) Tubo-Ovarian Abscess; (3) Myxomatous Degeneration of Myoma Uteri—Hysterectomy; and (4) Growth of Mesentery, associated with Intestinal Obstruction by Band.—Dr. A. G. Barrs: (1) A case of Chronic Posterior Basic Meningitis—recovering; and (2) Tumour of the Brain (Pons).—Dr. J. B Hellier: Double Solid Malignant Ovarian Tumour removed a fortnight after labour.—Dr. Allan: (1) Ostitis of the Tibia and Fibula after Chronic Ulcer; (2) Heart showing Dilated Pulmonary Artery and Lung with Infarcts from same; (3) Dilated Pulmonary Artery and Emphysematous Lung; (4) Dilated Pulmonary Artery from a subject with emphysematous lungs; (5) Large Kidneys; (6) Aneurysm of the Aorta and Very Small Kidney; and (7) Brain of an Epileptic—Dr. E. F. Trevelyan: (1) A case of Early Locomotor Ataxia, and another suspected case of the same disease, both with preserved knee jerks; and (2) a specimen of Tubercle Bacilli prepared from a hæmoptysis which occurred at the commencement of acute phthisis.

**BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.**—A meeting of this society was held on Jan. 29th.—Dr. J. Ivor Murray read a note on Hayling Island, where he had spent a fortnight, with the object of directing the attention of the society to the advantages of the island which was comparatively little known to medical men in London. He described the ozone-giving tidal mud of Langston Harbour, the tree-shaded roads, the golf-links, and the hard sands extending for miles and forming a very paradise for sea-bathers. The climate was mild, bracing, and remarkably free from rain and land fogs. The soil was mainly loam lying above chalk, with abundance of springs of good water. The place was a perfect one in which to reside in search of health, especially in the early stages of phthisis.—Dr. W Ewart inquired whether the island presented any hilly ground and whether the prevalence of any epidemic disease was on record. It was much to be desired that the Fellows of the society should address themselves systematically to the climatological survey of the United Kingdom, a task of considerable magnitude but one well within the scope and the purpose of the society.—Dr. Joseph Groves (Carisbrooke) said that Hayling Island was often visited by gales from the south-west.—Dr. R. Fortescue Fox and Dr. G. W. Hamilton Cumming also spoke.—Mr. William Armstrong (Buxton) read a paper on Adjuncts to Spa Treatment, their Advisability and Value. He said that although it had long been the custom at foreign health resorts to use special physical and dietetic methods in aid of their natural waters and baths English spas had lagged behind, and it was only comparatively recently that it had been thought well to press such measures into service. It had been too much the custom to order the baths and waters as a matter of routine or to deny to the patient any treatment except by air, rest, and change; but the old method of routine prescription and of the treatment of spa cases in batches was rapidly giving way to the treatment of the unit and the personal study of the individual. He ventured to formulate the following propositions: (1) that as spa physicians had often such limited periods in which to cope with chronic ailments, and as so many of the cases presented to them were complicated in character and refractory to treatment, it was desirable that they should have at command the best methods of approved physical treatment; (2) that such methods in no way diminished the reputation and value of the natural resources of the spas where they were used and were, as a rule, much more effective when used in combination with natural baths and waters; and (3) that the provision of proper arrangements for dietary at English bathing stations was of the highest importance and might well engage the attention of the medical profession in general and of the British Balneological and Climatological Society in particular.—Dr. Ernest Solly (Harrogate) said that at the English health resorts the hotel managers fancied that to provide an elaborate *table d'hôte* paid them better than to give facilities to patients to fare simply.—Dr. Scanes Spicer pointed out the urgent need for reform in the dieting arrangements existing at most English spas by the substitution of the restaurant system (as seen in Austria at Carlsbad and Marienbad) for the English *table d'hôte* meals. The objection to the latter was that they continued the temptation to overeat which beset the well-to-do Englishman, lessening or nullifying the results of the whole treatment in gouty states, obesity, and abdominal torpor.—Dr. F. A. de T. Mouillot, Dr. W. S. Hedley, Mr. W. Bowen Davies, and Dr. Fox also discussed the paper.

**MIDLAND MEDICAL SOCIETY.**—A meeting of this society was held on Feb. 5th, Mr. Arthur Oakes, the President, being in the chair.—Mr. L. P. Gamgee showed a child upon whom he had operated for Spina Bifida more than a year ago. The tumour was in the lumbar region and was of the size of a Tangerine orange. The sac was opened, those portions of it to which nerves and cord were not adherent were excised, and the two erector spinæ muscles were brought together over the cord by means of silk sutures. A separate row of sutures brought the edges of the skin wound together. The patient was now perfectly well in every way.—Dr. J. Douglas Stanley showed a case of Insular Sclerosis occurring in a boy, aged 12 years. The chief symptoms were very marked intention tremor, high-pitched voice, and some lingual paralysis. Nystagmus was present, but there was not great exaggeration of the tendon jerks.—Mr. A. Lucas read notes of a case of Perforated Duodenal Ulcer, one inch from the pyloric orifice, which occurred in a man, aged 20 years. The edges of the ulcer were brought together with a continuous silk suture and were further closed by two layers of interrupted sutures. A drainage-tube was left in the wound, the remainder being closed. The subsequent course of the abdominal condition was in every way satisfactory, but the patient developed broncho-pneumonia and died on Dec. 29th, 1901. The necropsy showed that there was no peritonitis, but there was a little lymph forming adhesions about the seat of perforation. The ulcer in the duodenum was soundly closed.—Dr. C. E. Purslow showed a specimen of Double Pyosalpinx which he had removed by abdominal section from a young single woman. The patient when admitted to the Queen's Hospital, Birmingham, dated her illness from an attack of influenza from which she had suffered 12 months previously; ever since then she had felt pain in the abdomen and for five months she had lost weight and strength and had noticed a swelling in the abdomen. The tubes were equally enlarged, containing about five ounces of pus in each. The patient made a good recovery and was now at work again. The interest of the case lay in the etiology: there was no evidence of gonorrhœa and the hymen was virginal; no signs of tubercle in the lung or elsewhere could be discovered. An examination of the pus was made by Dr. J. D. Stanley, pathologist to the hospital, and he reported that it contained no micro-organisms. Dr. Purslow was driven to the conclusion that the suppuration must have been due to the attack of influenza.—Dr. A. Douglas Heath read a paper on Some Types of Eczema and their Treatment.

**GLASGOW SOUTHERN MEDICAL SOCIETY.**—A meeting of this society was held on Feb. 6th, Dr. John Stewart, the President, being in the chair.—The subject for discussion was the Management of the Third Stage of Labour.—Dr. James K. Kelly introduced the subject and in doing so he remarked that the process naturally divided itself into the separation and then the expulsion of the placenta. He discussed the theories held regarding nature's method of separation and described the plan associated with the name of Credé After separation had taken place he recommended friction of the fundus of the uterus through the abdominal wall in order to strengthen the contractions and pleura, bladder, &c.—have been carefully revised and brought up to date. The changes which occur in the various organs throughout the body, especially in the circulatory organs, are duly recorded. The clinical symptoms of typhoid myocarditis, for instance, are minutely described. Dr. Curschmann points out that however alarming the disturbances due to this cause may appear to be they seem in general to be attended with little danger in cases of typhoid fever, especially when compared with the anatomically similar myocarditis of diphtheria. In the vast majority of cases, according to Dr. Curschmann's experience, complete subsidence of the symptoms takes place, and this is generally accomplished at the end of the febrile period, at times even somewhat earlier. He further states that he has never observed with certainty chronic myocarditis dependent upon typhoid fever. Some authorities have been inclined to lay stress on the cardiac affections which may follow in the train of typhoid fever, and there is evidently need for further clinical observations on this point.

Worthy of note are the remarks on Afebrile Typhoid Fever. The existence of this condition has been doubted, but the modern conceptions of the infectious diseases must of necessity lead to the belief that this fever may be wholly or almost wholly unattended with elevation of temperature, just as occurs in other infectious diseases, as, for instance, scarlet fever, measles, and variola. Dr. Curschmann agrees with the views of Strube and Fräntzel that these afebrile cases are not always of a mild character. He confirms the statement that severe fatal cases of typhoid fever in elderly, decrepit persons or in those debilitated by over-exertion, alcoholism, or chronic disease, may be entirely unattended with fever or may even be accompanied by a subnormal temperature. It would be interesting to know whether any such cases have occurred amongst the troops in South Africa. Considerable interest will naturally be attached to Dr. Curschmann's opinion on the value of the Widal serum diagnosis, upon which divergent opinions have been expressed. The value of the test has been challenged on the grounds that the reaction occurs even during health and in the presence of a number of diseases other than typhoid fever, especially apparently in acute infectious diseases. These apparent fallacies, however, have been explained; for it has been demonstrated that under the above-named conditions the reaction only takes place when comparatively large quantities of the serum to be examined are added to the culture. It has been found that the occurrence of agglutination with equal parts of serum and culture, even 1 of serum to 10 of culture, is of itself not conclusive of typhoid fever; and, further, that the development of the reaction with a dilution of 1 to 20, even 1 to 30 and 1 to 40, may also occur under other conditions, while a positive reaction with a dilution of the serum beyond 1 to 40 occurs almost exclusively in cases of typhoid fever. These observations should be borne in mind when the Widal reaction is tried; otherwise errors may arise, more particularly in children. A paragraph has been added by the editor on Preventive Inoculation. In common with most authorities, however, Dr Osler withholds a definite opinion but remarks that so far as the statistics yet reported from South Africa are concerned "the experience ...... is strongly in favour of inoculation"

Turning now to the part of the volume dealing with Typhus Fever we again find much that is interesting and instructive The etiology is naturally first considered, and the author remarks that "although we are quite certain that the contagion of typhus fever is a specific poison, elaborated solely within the body of the patient, and, therefore, undoubtedly referable to pathogenic micro-organisms, and although a great deal of useful investigation has been devoted to the subject, we are still in the dark as to its precise nature. Not one of the many micro-organisms brought forward up to the present time has gained complete recognition." Doubtless further investigation will in time solve the problem. In considering the origin and mode of transmission of the contagion Dr. Curschmann says: "Owing to the extreme facility with which the disease is carried from individual to individual sporadic cases of typhus fever are very rare." We cannot altogether agree with this statement. Epidemics of typhus fever are fortunately now of rare occurrence, but sporadic cases are not so uncommon as the author seems to indicate, nor is the infective power of such cases as marked as in the epidemic form. The morbid anatomy and symptomatology of the disease are described in a most interesting and thorough manner. The coloured plate of the eruption is a faithful reproduction of a characteristic case. The remarks on the differential diagnosis are also worthy of note.

In describing the treatment of the disease the author naturally lays great stress on the general management of the patient. He insists that the sick-room should be as large and airy as possible and afford the greatest amount of rest to the patient. He uses the term "open-air treatment" and states that he cannot say too much in favour of it. By adopting this measure he finds that the patients become quiet and that the violent headache and insomnia are more influenced by it than by any other means. The following sentence is also significant: "It is to the strict use of these measures that I attribute the fact that not a single physician was infected and that the percentage of hospital attendants who contracted the disease was conspicuously low during the three years from 1876 to 1878, when all the cases of typhus fever occurring in Berlin were admitted to Moabit and treated by the open-air method."

We welcome a translation into English of this excellent Encyclopædia of Practical Medicine. The first volume contains a vast amount of useful information and the forthcoming volumes will be awaited with interest.

*La Lutte contre la Tuberculose.* Par le Dr. R. ROMME, Préparateur à la Faculté de Médecine de Paris. Paris: Masson et Cie., Éditeurs Libraire de l'Académie de Médecine; *Gautier-Villars, Imprimeur-Éditeur. Pp. 190.* Price 2 francs 50 cents.

THIS little book is one of a series of the publications of the "Encyclopédie Scientifique des Aide-mémoire" which appear under the general editorship of M. Léauté, a distinguished member of the Institute of France. Up to the present time 300 volumes have been published, 24 having been produced each year; and of these one, "L'Alcoolisme et la Lutte contre l'Alcool en France," was contributed by Dr. Romme, the author of the present volume

Dr. Romme's book deals with the problems presented by the effects of tuberculosis viewed from the social and economical points of view. In France, as the author points out, the social aspects of tuberculosis are particularly urgent and that for more than one reason. In the first place, the population, instead of increasing, tends rather to remain stationary or to decrease. The loss to France through tuberculosis of 150,000 persons annually is a grievous one. This loss is the more severely felt because it deprives the country of the services of her citizens at a period of their lives at which in the ordinary course they would be most useful The disappearance of this living capital, Dr Romme says, is a terrible disaster, and he takes what we venture to hope is a too gloomy view of the future prosperity of his country, which is at present, he says, crushed by taxes and depressed by a decline of trade. The author goes on to point out, truly enough, that insanitary houses, want of light and of air, insufficient nourishment, overwork, and the abuse of alcohol—in a word, unhygienic conditions—play treatment by Finsen's method. The cases, which had been previously shown to the society, presented marked improvement on their former condition.—Dr. G. N. Meachen: (1) A case of Leucotrichia Annularis; (2) a Secondary Syphilitic Eruption in a Psoriatic; and (3) a case of Tuberculide.—Mr. Horace Wilson: Specimen of an Undeveloped Uterus and Appendages removed post mortem from an epileptic.—Mr. Herbert W. Carson: A case of Pylorectomy 12 months after operation. The patient had put on two stones in weight since the operation and was in perfect health.—Dr. Arthur E. Giles: Specimens of (1) Hydrosalpinx associated with Myoma Uteri and a Small Ovarian Dermoid; (2) Myoma in a Double Uterus; and (3) Malignant Kraurosis Vulvæ.—The meeting was well attended and the exhibition of cases and specimens gave rise to considerable discussion.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 30th, Dr. C. H. Willey, the President, being in the chair.—Dr. D. Burgess showed a young woman with Bifid Uvula and greatly Hypertrophied False Cords. The true cord looked like the folds of mucous membrane and the voice was produced by the false cords. The patient's mother had a cleft palate. Dr. Burgess also read notes (1) of a case of Ataxic Paraplegia due apparently to lead-poisoning, and (2) of a severe case of Transverse Acute Myelitis in which the legs were flaccid, the knee-jerks were absent, and there was complete loss of power and sensation for over a fortnight. The patient was able to walk out of the hospital two months after the onset of the illness.—Mr. R. J. Pye-Smith showed a boy, aged 14 years, on whom he had performed Peters's operation of extra-peritoneal transplantation of the ureters into the rectum for congenital retroversion of the bladder. Rectal tolerance of urine had been soon established and the boy's condition had greatly improved during the four months that had elapsed since the operation.—Dr. W. S. Porter showed a specimen of Cerebral Tumour (glioma) and read notes of the case.—Dr. A. J. Hall read a paper on the Varieties of the Ringworm Fungus, their Clinical, Microscopical, and Cultural Characteristics, with some Observations as to their Distribution in the Sheffield District. The paper was illustrated by numerous microscopical preparations, cultures, photographs, &c.

# Reviews and Notices of Books.

*Nothnagel's Encyclopedia of Practical Medicine: Typhoid Fever and Typhus Fever.* By Dr. H. CURSCHMANN, Professor of Medicine, Leipsic. Edited, with Additions, by WILLIAM OSLER, M.D., Professor of the Principles and Practice of Medicine, Johns Hopkins University, Baltimore. Authorised Translation from the German under the Editorial Supervision of ALFRED STENGEL, M.D., Professor of Clinical Medicine in the University of Pennsylvania. London and Philadelphia: W. B. Saunders and Co. 1902 Pp. 646. Price £1 1*s*.

THE excellence of the series of monographs issued under the editorship of Professor Nothnagel has been recognised by medical practitioners sufficiently familiar with German to read these works, and the publication of an English edition will doubtless be most favourably received. A set of 10 volumes will be issued representing the most practical part of the work. These volumes will contain the essence of the entire work and the present series of essays has been selected with especial regard to the needs of the practical physician. At some later date volumes will be published on the more special and scientific subjects

As indicated by the title, the volume now under consideration contains a translation of Professor Curschmann's important work on Typhus and Typhoid Fevers. The translator (Professor Alfred Stengel) has performed his task admirably and the value of the work is further added to inasmuch as Professor W. Osler has acted as editor and has made additions to the text where it has been deemed desirable. With the consent of Professor Curschmann these additions have been made so as to run smoothly with the original text. Numerous changes, necessitated chiefly by the work which has been accomplished since the issue of the German edition, have been thus made. To some of these we shall again refer.

Typhoid fever is first considered, and the essay is divided into sections instead of into chapters. The Morphology and Biology of the Typhoid Bacillus are fully discussed, and then follow some interesting remarks on the Vitality of the Typhoid Bacilli. The investigations of Chantemesse are referred to. This observer showed that artificially prepared and especially carbonated waters may in times of epidemic play an important rôle in the dissemination of the disease when used as presumably innocuous substitutes for ordinary drinking water. Typhoid bacilli have been found to retain their vitality in them for days, and even for weeks.

In dealing with the etiology of the disease another fact to which attention is drawn is that the bacilli of Eberth are relatively resistant to the secretions of the stomach, so that they may leave this viscus with their vitality preserved, especially if mixed with certain articles of food. Well worthy of perusal are the remarks on the Most Important Carriers and Modes of Dissemination of the Virus. Water is, of course, the main source by which infection is carried, although the germs may occasionally be conveyed in the dry state by being attached to particles of dust. The author entirely discards the theory that typhoid fever results from the swallowing or inhalation of putrid gases. This is in accord with modern bacteriological knowledge, although the idea is still held by those who have not followed scientific research.

We cannot express entire satisfaction with the arrangement of Section II. which is headed Pathology. The section is divided into a number of sub-sections. The first deals with the general "symptomatology" of the disease and a picture is sketched in outline of a moderately severe case of typhoid fever terminating in recovery in a previously healthy adult. A summary follows of the post-mortem conditions and then the clinical side is returned to, and an analysis is given of the individual symptoms and complications. Although each sub-section is excellent in itself the alternation between the pathology and symptomatology is confusing. The sub-section on the morbid anatomy has been brought fully up to date by the editor. The researches of Mallory are mentioned. He concluded that the changes which occur in the Peyer's patches are due to the action of a toxin produced by the typhoid bacillus and that a proliferation of endothelial cells ensues. These cells are phagocytic in character, and the swelling of the intestinal lymphoid tissue is due almost entirely to their formation. The necrosis, he thinks, is due to occlusion of the veins and capillaries by fibrinous thrombi which owe their origin to degeneration of phagocytic cells beneath the lining endothelium of the vessels. He describes a similar process occurring in the mesenteric glands and the spleen. These views are interesting as formulating a new theory on the formation of the intestinal lesions.

Dr. Curschmann's observations on the temperature curve are most instructive. Too much attention cannot be paid to the intermittent and remittent febrile types described and to the great irregularities of such curves. An observer who is unfamiliar with, and incapable of, interpreting them is exposed to the liability of great error in diagnosis and prognosis. The typical temperature curve in typhoid fever is well known, but atypical curves frequently occur, and the practitioner should be acquainted with this fact so as to avoid falling into serious error.

Much valuable work has recently been accomplished with regard to the changes which occur in the condition of the blood during typhoid fever. The results have been included in this volume. Thayer's exhaustive studies have been utilised, and the paragraphs on the localised lesions due to the bacillus—particularly of the bones, meninges, heart, who wishes to have a clear idea of the origin and course of the present South African War The facts are plain and there are no rhetorical flourishes to make out that black is white From the preface we learn that Dr Conan Doyle and his publisher wish to translate it into all European languages and to send a free copy to every deputy and every newspaper on the continent and in America We do not suppose for one instant that Dr Conan Doyle's *resumé* will have the slightest effect upon the baser kind of continental detractor of the British Army or upon the unpatriotic kind of person of our own country who writes about "Hell in South Africa," or who seizes upon flying rumours to put "Reported Loss of a British Transport" upon a newspaper poster, or who talks about "methods of barbarism" Such people would not believe if an angel came down from Heaven and told them that the war was being waged with as much humanity as is consistent with any war But for those who are merely ignorant Dr Doyle's little book will be as a light shining in a dark place An appeal is being made to the public for funds to further the distribution of the book and we are sure that it will be well responded to

*The Harveian Oration, delivered before the Royal College of Physicians of London on Oct 18th, 1901* By NORMAN MOORE, M D Cantab London John Murray. 1901 Pp 59 Price 2*s* 6*d* net —We are glad to see Dr Norman Moore's Harveian Oration reprinted in a form so handy to read as the volume now before us Everyone who heard Dr Moore's scholarly oration delivered, or who read it as printed in our issue of Oct 26th, 1901 (p 1097), will welcome it Dr Norman Moore had an inspiriting theme and he treated it in his own fashion He is always happy in his literary treatment, and whether he is discussing the pathological processes which led to the death of Chlodowig, or Merlin—if indeed he be dead—or talking about Celtic mysticism or disputing on the difference between the Bogomiles and the remnant of the Christians of St Thomas, he is always interesting Mr Murray is to be warmly commended upon the style in which he has issued the Oration

*Gonorrhœal Arthritis* By L VERNON-JONES, M D Dub London H K Lewis Crown 8vo, pp 52. Price 2*s* 6*d* —This little book consists of three chapters dealing respectively with the pathology, symptoms, and treatment of gonorrhœal arthritis With regard to the first Dr Vernon-Jones has taken the trouble to collate the various bacteriological information on the subject and states the position of our knowledge clearly if rather narrowly This chapter is the most satisfactory of the three, for the two others are very attenuated The preface explains the appearance of this little book by the "absence of any work on the subject" This being so, Dr Vernon Jones should certainly have gone more exhaustively than he has done into the important question of adequate treatment for this far from uncommon complaint So far as his work goes it is good, but having embarked upon it we wish he had gone further

*The Lemco Cookery Book.* Compiled by Mrs H M YOUNG London Liebig's Extract of Meat Company, Limited 1902. —This is a handy little book, containing 180 everyday receipts for soups, fish, entrées, poultry and game, gravies, sauces, and sweets, with a few novel invalid dishes Its object is to point out that the Liebig Company's Extract of Meat will mix with everything to the advantage of the dish, and, though the author may be thought to protest too much, those of the recipes that we have tried were thoroughly successful We understand that the Liebig Company is distributing a quarter of a million of these cookery books from house to house

## JOURNALS AND MAGAZINES.

*The Medical Magazine* for January contains one article of unusual merit. This is a contribution from Dr G H Savage upon "Conditions other than Heredity as Causes of Insanity," and it is worthy of perusal by every practitioner Moreover, the originality and simple clearness of Dr Savage's method of demonstrating his facts and theories make this address an unusually pleasing piece of reading The main theme of Dr Savage's article is contained in a passage near the beginning, where he says that "very much of the mental disorder which we meet arises from the immediate surroundings of the individual, and that certainly in many cases the sufferer is the cause of his own trouble" This is not only a true but a cheering view of the case, for where all steps are not precluded by the fixed idea of an inevitable hereditary taint patient and practitioner will alike approach treatment with sanguine determination The rest of the magazine deals mainly with legislation and statistics

## THE CALLIANO BELT FOR THE PREVENTION OF SEA SICKNESS

MESSRS ARMAND CLICQUOT AND CO, of 19, St Dunstan's-hill, London, E C, have submitted to us two specimens of a belt for the prevention of sea-sickness which is the invention of Dr Calliano, an Italian medical man The belt is made of jean or some similar substance, stiffened in places with "bones" In fact, it is like an ordinary waistbelt, and is about six inches in depth The novel feature of the belt is a heart shaped pad affixed to the middle of the belt The method of use is as follows The belt is buckled round the chest next to the innermost garment, the apex of the pad being uppermost and fitting into the apex of the costal angle The centre of the pad thus presses on the epigastrium, and pressure can be regulated to any extent by means of a screw. An abdominal belt of some kind has long been known as a good thing for sea sickness and is supposed to act by pressure on the viscera In Dr. Calliano's belt the pressure is more particularly directed to the cœliac plexus We submitted two belts for trial to two travellers In one instance, however, the belt did not get a fair test as the Channel was crossed in a dead calm The other traveller who kindly consented to try the belt for us was a lady going by sea to Tangier She started from Southampton and crossed the Bay of Biscay in very rough weather We give her experience in her own words "I buckled it on the first morning and found it most uncomfortable I had to wear it without stays and I cannot say it was anything but disfiguring and I felt qualms all day and after dinner was very sick, so next day I did not wear the belt as I thought I might as well be sick in comfort" Of course, it is impossible to judge of the value of this appliance from one instance and it is only fair to say that Dr. Calliano says that the belt does no good in the nervous form of sea sickness. Also plenty of people have apparently testified that the use of the belt has prevented them from being sea-sick But that there is any one cure for sea sickness we do not believe We fear that the disfigurement alluded to by our "tryer" will be fatal to the extensive use of the belt by the female sex. If a woman is sick in her cabin no one need see her, but if she is seen in an unbecoming belt and is not sick she will probably be more uncomfortable than if she were ill and unseen But for the mere man we think it very likely that in certain cases Dr Calliano's belt will prove very useful a great part in causing the spread of tuberculosis, and a part perhaps as important as the inhalation of the bacillus of Koch. The book was written to show what means have been adopted for the prevention of the disease and to supply the evidence necessary to appraise these at their proper value. After a preliminary chapter on the etiology of tuberculosis in its social aspects the author gives an account of pulmonary tuberculosis in its relations to the conditions of work in England. He then describes the German "sanatoriums," the way in which the money is provided for their support, and the manner in which they are managed. In the last chapter he insists on the necessity from a national point of view of the establishment of sanatoriums in France. Amongst the appendices there is a rather curious document called a "catechism against tuberculosis" which has been drawn up by one of the local sections of the "Ligue Nationale Belge contre la Tuberculose." This catechism teaches as articles of obligation that 90 per cent. of the total number of cases of tuberculosis are derived from infected sputa and that tuberculosis is curable, but that the cure is difficult and can only be carried out under special conditions, that neither the rich nor the poor can carry out these conditions at home—that the cure can only be effected at "special establishments." The case for sanatoriums does not need, and will be prejudiced by, such statements

The book itself is well written, the facts are clearly stated, and the arguments founded on them are logical. It should be read by everyone interested in the subject—and it is a subject of universal concern.

*Handbook of Bacteriological Diagnosis for Practitioners, including Instructions for the Clinical Examination of the Blood.* By W. D'ESTE EMERY, M.D., B.Sc. Lond., Lecturer on Pathology and Bacteriology in the University of Birmingham. London: H. K. Lewis. 1902. Pp 215 with two plates. Price 5*s*. 6*d*.

FOR this excellent book, one of "Lewis's Practical Series," we have nothing but praise. It is eminently practical, concise, and accurate. To instruct the practitioner how to make his own bacteriological diagnosis, or, if this be not possible owing to lack of appliances, to teach him how to collect and to send material so that it may reach the expert in such a condition that it may be satisfactorily examined and a trustworthy report furnished, is the perfectly definite aim of the author, and he does not allow himself to stray from the direct path to his object. How often material is not properly collected and sent the expert knows only too well. With the author's opinion that a bacteriological examination which is made by one person and interpreted by another, or which is made on material which has passed through more hands than one, loses much of its value, we thoroughly agree.

The book is divided into three parts, treating respectively of Apparatus and Processes, the Diagnosis of certain Diseases, and the Collection and Examination of certain Morbid Materials. The instructions in the first part are clear and accurate and are evidently written by a practical worker and teacher. Of course, opinions differ as to the relative value of methods and the details of their execution; thus we see no advantages in the method described for the inoculation of tubes over the old plan and should reverse the advice as to the form of pipette (p. 42) to be chosen for the collection of blood for Widal's reaction and for cultural examinations respectively. In describing spore staining in anthrax (p. 67) a confusion of two methods has crept in; dilute sulphuric acid is used to decolourise the bacillus, but in the next sentence the decolourising agent is spoken of twice as spirit. The second part is also very good both in the restraint the author shows in the selection of materials to be examined and the methods to be employed as well as in the sobriety and common sense of the interpretations of the results. The only exception we take is to the implied medico-legal value of the microscopical examination for the gonococcus. There is a mistake in the reference on p. 57 to the figure of the tetanus bacillus. The diagnosis of enteric fever is carefully described and the successive steps of the method should be easily followed. Stress is rightly laid upon obtaining sufficient blood for the examination; it is a common complaint that too scanty a supply is sent. The test does not require much blood and the amount can usually be easily obtained in a pipette drawn out at each end without employing suction. The examination of hairs for the ringworm fungi is well described. The third part concerns the collection of morbid materials. Throughout this portion, as indeed throughout the whole book, there is an appreciation of the difficulties met with by the practitioner cut off from laboratory appliances and there are many excellent practical hints for meeting these difficulties. The methods for the collection of spinal fluid by lumbar puncture and for obtaining blood are fully given. The book ends with a description of methods for cutting and staining sections. We would strongly recommend this book to practitioners.

*Selected Researches in Pathology.* By A. GUNN AULD, M.D. Glasg., M.R.C.P. Lond. With Illustrations. London: J. & A. Churchill. 1901. Pp. 160. Price 6*s*.

THIS volume contains a selection from Dr. Auld's investigations in various branches of pathology. Most of the results have from time to time been brought before some of the medical societies and subsequently published in Transactions and medical journals. The essay on Emphysema and that on Bright's Disease appeared in our own columns; in the volume now under consideration the remarks on the latter condition have been re-written and new observations are incorporated.

Perhaps the most interesting chapters in the book are those on Pneumonia. The subject-matter relates entirely to the pneumococcus, or diplococcus lanceolatus of Fraenkel, its chemical pathology, and the action of its toxins in rabbits. The pneumococcus is a difficult organism to work with, owing mainly to the fact that its virulence quickly dies out. Dr. Auld finds, however, that when preserved in blood the organism will retain its virulence for months. The method which he employs is to take up the blood from the heart directly with a small specially made pipette. The ends of the pipette have each a constriction near the bulb (in its centre). The bulb being filled, or nearly so, with the blood, the constrictions are sealed by heat. Preserved in this fashion the organisms remain active for months.

Dr. Auld's experiments relating to the methods devised for raising the strength of pneumococcus toxin and the effects produced by the injection of the toxins into rabbits in connexion with the process of immunising are rather difficult to follow; he himself admits that the research is "only fragmentary," nevertheless certain interesting results were arrived at. It is known that some individuals suffer more than once from an attack of pneumonia. Dr. Auld shows that the action of the toxin of pneumonia is injurious, and that this action is of very long duration, far outliving the presence of the immunising "anti-bodies." To this prolonged action he ascribes the susceptibility to future attacks.

Other chapters in the book deal with hæmatogenous jaundice, Addison's disease, atheroma, and aneurysm, the chapters on the two last-named conditions being the joint production of the late Professor Coats and Dr. Auld.

## LIBRARY TABLE.

*The War in South Africa: its Cause and Conduct.* By A. CONAN DOYLE. London: Smith, Elder, and Co. Supplied through George Newnes, Limited. 1902. Pp. 156. Price 6*d*.—This unpretending little book should be read by everybody ost prevalent. Probably in no part of the world is scess of the liver more frequently met with than in India, d therefore a discussion between officers of the Indian edical Service on the Surgical Treatment of Hepatic bscess must be of interest for surgeons all over the world.

paper on this subject was read recently by Lieutenant-olonel J. MAITLAND, I.M.S., before the South Indian ranch of the British Medical Association, and in the scussion which followed many other surgeons joined, and e lessons to be learned from their remarks may well be corded. For abscess of the liver, though rarely seen in is country, is not unknown. We have now practically andoned the etiological distinction between the solitary scess of the liver and the multiple abscess, the former ing considered the type of the tropical abscess and the tter the form met with in temperate zones; though is recognised that in the multiple variety the bacterial fection is probably different. It cannot now be doubted at in both forms of hepatic abscess intestinal ulceration the starting-point of the disease and that dysentery is e most common form of ulceration of the bowel which ives rise to abscess of the liver.

The opinions maintained in this recent discussion at adras may be set forth as follows. That the pus should e evacuated as soon as it is diagnosed all surgeons agree, ut the diagnosis of the presence of pus is intimately ssociated with the treatment. Sometimes the symptoms nd the local signs are very distinctive so that there can e no room for doubt as to the existence of an abscess, specially when the abscess is very large or very near the rface of the liver. If, however, the suppuration should e deeply seated the diagnosis becomes much more difficult nd it is in these cases that many surgeons are inclined to avour an exploratory puncture with a hollow needle for the urpose of diagnosis; but this view found no favour at e Madras discussion. That by this method the presence f pus may be ascertained is obvious, but against the ractice there are many and weighty objections on hich Lieutenant-Colonel MAITLAND laid much stress. In he first place there is great risk of hæmorrhage. It as been said that the chief danger of bleeding rises from a possible wound of the inferior vena cava nd, therefore, it has been recommended that the eedle should not be allowed to penetrate more than four nches, for then the vena cava could not be injured. This dvice would be sound if the hæmorrhage could come only rom this vessel, but it cannot be doubted that the liver ubstance may bleed, even to a fatal issue, although no essel of any great magnitude has been wounded, and Lieutenant-Colonel MAITLAND in his paper quoted a ase in which he had seen this unfortunate result ccur. Great as is the danger from hæmorrhage, greater still is the risk from infection of the peritoneum. It is quite exceptional for the peritoneal surfaces over the abscess to be adherent, and, therefore, if the exploring needle has met with pus, it is almost inevitable that as the needle is withdrawn a drop or two of pus will be left in the peritoneal cavity, though if the operation for evacuation of the pus follows immediately on the exploratory puncture the danger of setting up a general peritonitis will be much lessened. Moreover, as Captain W. J. NIBLOCK, I.M.S., pointed out, it may happen that great difficulty may be experienced in finding the abscess at the second operation, although the exploring needle had previously shown the presence of pus. Therefore, it may be laid down with certainty that if any exploratory puncture be made the operation of emptying the abscess should follow immediately. Since in most cases of hepatic abscess the right lobe is implicated the transthoracic operation is generally required. A hollow needle is first introduced and when pus has been found an incision close to the needle, with or without resection of a portion of a rib, lays open the pleura, the two surfaces of which are stitched together around the wound. The diaphragm is next divided, with its subjacent peritoneum. The two peritoneal surfaces may then be stitched together or gauze packing may be used. The pus is best evacuated, not by any form of aspiration, but by incision. There is no real danger of hæmorrhage from the substance of the liver when the wound is visible, for packing with gauze will always restrain it. The further stages of the operation are simple—the abscess cavity is irrigated and drained and treated in accordance with ordinary surgical principles. The results are eminently satisfactory, the general rate of mortality being very low.

Such may be looked upon as the most modern method in India of treating the solitary abscess of the liver and the most experienced surgeons in Europe would not suggest any more than unimportant modifications of this operation. In this country we hear too little of the very extensive, arduous, and important work which is done by our colleagues in distant dependencies of the British Crown. With the unrivalled opportunities they possess for the diagnosis and treatment of the diseases prevalent in tropical and subtropical climates, their conclusions and methods of practice should prove of the greatest value to surgeons in all parts of the empire, and the record of their work will always be received with full appreciation in this country.

## Surgical Operation for Mitral Stenosis.

A NOTE by Sir LAUDER BRUNTON published in our columns last week contains a sufficiently heroic therapeutic suggestion. It calls attention to the grave effects of stenosis of the mitral valve and to the possibility that relief might be obtained by a surgical division of the diseased valve. With an ambition to bring relief to these patients Sir LAUDER BRUNTON obtained a licence and certificates a year ago to enable him to test on animals the validity of his suggestion. We gather that he has proceeded no further than the table of the dead-house in making his investigation, and having many other claims upon his time he now publishes the suggestion in the hope that others will complete what he has begun. This is a somewhat unusual course to pursue and we think that Sir LAUDER BRUNTON would have been better advised to have himself completed his experiments, even at considerable inconvenience, rather than to incite others to pursue a path into the unknown which must be beset with very grave difficulties and responsibility. The experiments on animals which he advocates require considerable delicacy

## Panics and Publicity.

IN the dark days of 1899, when untoward events in South Africa cast a heavy gloom over all men's minds and were filling their mouths with bitter reproaches or hopeless anticipations, there were not wanting, especially among the older members of the community, those who deplored the amount and facility of news. Little reverses, they said, were placarded, published, and talked about till they assumed the size of real disasters; and a loss of men which in the days of WELLINGTON, for instance, would have gone unknown for months, and would have been disregarded when realised, set people nowadays in a perfect fever of alarm and apprehension. Like a story repeated from mouth to mouth, a piece of news lavishly printed becomes wildly exaggerated. A slight reverse, well headlined, placarded at every street corner and discussed in every club, assumes the proportions of a great defeat. A little space of time shows the true proportion of things, and by to-day people are ashamed of the fears that they allowed to possess them in the early times of the South African Campaign. We deeply sympathise with the apprehensions of those who have relatives and dear friends at the war, but they, in common with the rest of the public, have learned that sensational and inaccurate word-pictures save no lives and allay no fears, but serve rather to depress the *morale* of the country.

Yet the lesson has not been so well learned but that a small epidemic of small-pox in London is able to create what almost amounts to a panic in the minds of people all over the United Kingdom. The fear to which the present attack of small-pox has given rise in some breasts would be ludicrous were it not that such terrors, however ill justified, have a serious effect upon the business of the nation and the prosperity of London. It is hardly credible that an epidemic like the present—a little epidemic in which, roughly speaking, one person in 7000 has been attacked—should give rise to anything approaching panic anywhere. Yet such is in reality the case. There is definite evidence, not only that private individuals shrink from visiting London in the usual way, but that business is interfered with by a dread of the epidemic, and that even the rents of houses for viewing the Coronation procession months hence have fallen enormously. Such a state of alarm is unreasonable and ill-advised, and is, we feel sure, merely an unintended effect of that general newspaper publicity to which allusion has already been made. A man reads of 30 fresh cases in large type, thinks the times of pestilence are here again, and fears that London is unsafe. The next day he learns that the fresh cases amount to 90 and that in the opinion of a leader writer the local authorities are supine, or the London County Council is inept, or the medical profession is ignorant—or all three. He is thus confirmed in his uneasiness. Much more rightly he should reflect that with vaccination and revaccination and ordinarily healthy surroundings he is practically rendered immune, so far as small-pox is concerned. He has no excuse in the lack of good example. Always of sound judgment and correct action where medical matters are concerned, HIS MAJESTY THE KING has never pointed the proper course with an apter hand than he is doing at the present time as regards London and the small-pox. The entire Royal Household having been submitted to revaccination the Royal Family stay largely in London and frequent public places with the most conspicuous freedom. Whether such action is or is not taken with the direct intention of restoring confidence that may be shaken in the absolute safety of London, at any rate it should make timid citizens ashamed not to follow the footsteps of the KING when the path of wisdom that he treads is as open to the lowest commoner as it is to Royalty itself. Vaccination, revaccination and cleanliness are available for every inhabitant of this country. Let men and women avail themselves of the aid which medical science puts before them and lay aside fear, one of infection's closest allies, and they need not hesitate to dwell in London or anywhere else where an outbreak of small-pox is all that terrifies them. This advice is certain to be given by our readers. We wish that our brother journalists who appeal to the great public would take the same line. It is really important that the country at large should know that London is not a city of death, to be avoided by the business man and the pleasure-seeker alike, for the welfare of the whole empire is inextricably bound up with the fortunes of the capital.

One more consideration should shame people out of fear in the present instance. No Englishman, probably, would care to admit to feeling fear where a Frenchman was fearless. Yet this very London epidemic that is causing so much alarm is probably the offspring of a more serious outbreak in Paris that gave rise to a far less amount of apprehension. It will be a new circumstance in the history of this nation if we have to point to the imperturbability of the Parisian and to beg our countrymen to endeavour to imitate it under similar circumstances. Small-pox is a loathsome disease and may well be dreaded. We are not belittling the need for all possible precaution. But what we wish to insist upon is this, that against small-pox we have happily an admirable safeguard in proper vaccination and revaccination. Let the present outbreak make Englishmen and Englishwomen insist upon the proper utilisation of these preventive measures in their own cases, and in the cases of those dependent upon them. Then let them face the situation, by no means a terrible one, with the imperturbability that has hitherto always been associated with our national character and that is at the present time so finely exemplified by the reigning Sovereign.

## The Surgical Treatment of Hepatic Abscess.

WHEN we seek to discover the latest teaching as to the treatment of any disease it is but natural that we should turn to those countries where the disease in question is most prevalent. Probably in no part of the world is abscess of the liver more frequently met with than in India, and therefore a discussion between officers of the Indian Medical Service on the Surgical Treatment of Hepatic Abscess must be of interest for surgeons all over the world. A paper on this subject was read recently by Lieutenant-Colonel J. MAITLAND, I.M.S., before the South Indian Branch of the British Medical Association, and in the discussion which followed many other surgeons joined, and the lessons to be learned from their remarks may well be recorded. For abscess of the liver, though rarely seen in this country, is not unknown. We have now practically abandoned the etiological distinction between the solitary abscess of the liver and the multiple abscess, the former being considered the type of the tropical abscess and the latter the form met with in temperate zones; though it is recognised that in the multiple variety the bacterial infection is probably different. It cannot now be doubted that in both forms of hepatic abscess intestinal ulceration is the starting-point of the disease and that dysentery is the most common form of ulceration of the bowel which gives rise to abscess of the liver.

The opinions maintained in this recent discussion at Madras may be set forth as follows. That the pus should be evacuated as soon as it is diagnosed all surgeons agree, but the diagnosis of the presence of pus is intimately associated with the treatment. Sometimes the symptoms and the local signs are very distinctive so that there can be no room for doubt as to the existence of an abscess, especially when the abscess is very large or very near the surface of the liver. If, however, the suppuration should be deeply seated the diagnosis becomes much more difficult and it is in these cases that many surgeons are inclined to favour an exploratory puncture with a hollow needle for the purpose of diagnosis; but this view found no favour at the Madras discussion. That by this method the presence of pus may be ascertained is obvious, but against the practice there are many and weighty objections on which Lieutenant-Colonel MAITLAND laid much stress In the first place there is great risk of hæmorrhage. It has been said that the chief danger of bleeding arises from a possible wound of the inferior vena cava and, therefore, it has been recommended that the needle should not be allowed to penetrate more than four inches, for then the vena cava could not be injured. This advice would be sound if the hæmorrhage could come only from this vessel, but it cannot be doubted that the liver substance may bleed, even to a fatal issue, although no vessel of any great magnitude has been wounded, and Lieutenant-Colonel MAITLAND in his paper quoted a case in which he had seen this unfortunate result occur. Great as is the danger from hæmorrhage, greater still is the risk from infection of the peritoneum. It is quite exceptional for the peritoneal surfaces over the abscess to be adherent, and, therefore, if the exploring needle has met with pus, it is almost inevitable that as the needle is withdrawn a drop or two of pus will be left in the peritoneal cavity, though if the operation for evacuation of the pus follows immediately on the exploratory puncture the danger of setting up a general peritonitis will be much lessened. Moreover, as Captain W. J. NIBLOCK, I.M.S., pointed out, it may happen that gre difficulty may be experienced in finding the abscess at th second operation, although the exploring needle had pre viously shown the presence of pus. Therefore, it may be lai down with certainty that if any exploratory puncture be mad the operation of emptying the abscess should follow imme diately. Since in most cases of hepatic abscess the righ lobe is implicated the transthoracic operation is generally required. A hollow needle is first introduced and when pus has been found an incision close to the needle, with or without resection of a portion of a rib, lays open the pleura, the two surfaces of which are stitched together around the wound. The diaphragm is next divided, with its subjacent peritoneum The two peritoneal surfaces may then be stitched together or gauze packing may be used. Small-pox is a loathsome disease and may well be dreaded. We are not belittling the need for all possible precaution. But what we wish to insist upon is this, that against small-pox we have happily an admirable safeguard in proper vaccination and revaccination. Let the present outbreak make Englishmen and Englishwomen insist upon the proper utilisation of these preventive measures in their own cases, and in the cases of those dependent upon them. Then let them face the situation, by no means a terrible one, with the imperturbability that has hitherto always been associated with our national character and that is at the present time so finely exemplified by the reigning Sovereign.

## The Surgical Treatment of Hepatic Abscess.

WHEN we seek to discover the latest teaching as to the treatment of any disease it is but natural that we should turn to those countries where the disease in question is

rate, there is certainly a relationship between character and climate.

## SMALL-POX IN LONDON.

THE small-pox returns for the past week show the following figures. On Saturday, Feb. 8th, there were 32 fresh cases notified and removed, on Sunday, the 9th, there were 23 fresh cases; on Monday, the 10th, there were 48 fresh cases; on Tuesday, the 11th, there were 58 fresh cases; and on Wednesday, the 12th, there were 58 fresh cases. With regard to the question to which we referred last week of the vaccination or revaccination of the employés of large firms, Messrs. Bradbury and Wilkinson in a letter to the *Times* of the 10th, stated that although they had made arrangements for offering vaccination to their employés, the operation could not be carried out because the public vaccinator was unable to vaccinate any person living outside his own district. Messrs. Octavius H. Smith and Co., in a letter to the *Times* of the 11th, also stated that the public vaccinator for their district pointed out this difficulty. Messrs. Smith, however, thereupon wrote to the Local Government Board who granted the public vaccinator special leave to vaccinate any of Messrs. Smith's employés although they did not reside in his district.

## THE METROPOLITAN WATER-SUPPLY.

THE report on the condition of the metropolitan water-supply during the month of December, 1901, has recently been issued by the Local Government Board. The Water Examiner states that the water of the Thames was in good condition at Hampton, Molesey, and Sunbury from the 1st to he 12th and from the 19th to the 24th days of the month under review. The engineer to the Chelsea Waterworks Company reports that on the 13th, 18th, and 25th days of the month the water at West Molesey was of "indifferent" haracter, and that from the 14th to the 17th and from he 26th to the 31st the state of the water was "bad." During the whole of the period at which the water was nd the intake of the Chelsea Company was closed. In he case of the Southwark and Vauxhall Company the river ntake to the filters at Hampton was open from the 1st to the 0th of the month. On Dec. 30th Dr. T. E. Thorpe, the nalyst to the Local Government Board, found that taking he average amount of organic impurity in a given volume the Kent Company's water during the nine years ending ecember, 1876, as unity, the proportional amount in an ual volume of the Southwark Company's water amounted no less than 3 6. On the same day the water supplied by e Lambeth Company showed an even greater amount of ganic impurity (5 3) as judged by the same standard, t the worst water of all was that supplied by the and Junction Company on Dec. 31st, which gave a comrative result represented by the figures 5 4. On Dec. 30th e Lambeth Company's water was very faintly opalescent. e Thames at its highest point during the month was one t three inches above, and at its lowest one foot below, the rage summer level. The rainfall during the month at st Molesey was 3 05 inches. The average total daily ount of water distributed by the companies was 197,577,154 lons for a population estimated at 6,307,230, and this resents a daily consumption per head of 31 33 gallons for purposes. The company which is stated to supply the est daily amount per head is the Grand Junction, and the which supplies the smallest amount is the East London, figures given being respectively 42 06 gallons and 25 87 ons. With the exception of the Lambeth Company all metropolitan companies supplied less water per head ng the month than that given in December, 1900. companies which now profess to give a constant water-ice to their customers are the Chelsea, the East London, the Grand Junction, and the West Middlesex. Of the oth companies the Kent, the New River, and the Southwar and Vauxhall supply respectively 95·9, 95 7, and 93 0 p cent., as compared with 92·3, 95·0, and 93·2 per cent. i December, 1900. The Lambeth Company professes to gi constant service to no more than 77·5 per cent. of its customers The proportions of brown tint observed in a two-foot tub varied very greatly in the different samples examined; i ranged from two to 30 degrees of the standard in use The brown tint which is due to the presence of foreig matter or dirt is well marked in the water supplied by those companies which have a deficient storage capacity or an insufficient filtration area at those periods at which turbid water is taken from the Thames for immediate use. The water of the Lambeth Company exhibited the deepest average tint of brown. Dr. Thorpe says of a specimen of the Southwark Company's water that it "was good for the time of year"—a statement which seems to require elucidation. All the samples taken of the water supplied by the Kent Company were of their usual excellent quality.

## FOREIGN MEDICAL PRACTITIONERS IN LONDON: SOME INTERESTING FIGURES.

ACCORDING to the recently issued census returns there are 4801 "physicians, surgeons, and general practitioners" in London, of whom 92 are females. There are no less than 169 male and six female foreign physicians, surgeons, and general practitioners located in London. Of these, there are nine male and one female who are Russians; one male Russian Pole; seven male, three female, Swedes; two male Norwegians; three male Danes; four male Dutch; one male Belgian; 12 male French; 32 male, one female, Germans; three male Austrians; eight male Swiss; three male Spaniards; one male Portuguese; 12 male, one female, Italians; two male Greeks; three male Turks; two male Japanese; one male Asiatic; and 63 male Americans. 16,107 persons living in London are returned as "sick nurses, invalid attendants," of whom 15,844 are females; three of the latter are stated to be blind. 266 "midwives" are also returned in London. There are 62 female dentists in London.

## POISONING BY CUTANEOUS ABSORPTION OF ANILINE.

IN the December number of the *Archives Générales de Médecine* Dr. Georges Brouardel of Paris has collected particulars of several cases of poisoning due to the wearing of boots to which a black material containing aniline had been recently applied. The patients were mostly children from the age of 17 months upwards, but at least two of them were adult males. The attacks occurred during hot or moderately warm weather. Attention was first called to this particular form of aniline poisoning by Dr. Landouzy and Dr. Brouardel, who brought it before the Paris Academy of Medicine in July, 1900. The boots seem to have been in all cases of yellow leather, the colour of which was changed to black either because they had become shabby or because the wearers happened to be in mourning. The symptoms were quite similar to those which have from time to time been presented by workers in aniline factories and usually appeared in from one hour to three or four hours after the boots were put on. Generally, before the patients felt themselves ill their paleness and the remarkable blueness of their lips and fingers had attracted the attention of those in their company; this stage was soon followed by giddiness, shivering, increased cyanosis, muscular relaxation, and loss of consciousness, either partial or complete. In severe cases this condition persisted for about 24 hours, but in mild cases for only a short time. No deaths occurred. The boots

and skill on the part of the experimenter, and we have a strong feeling that the man with whom the idea originated is certainly the most fitted to cope with the initial difficulties and to bring the experiments to a satisfactory conclusion, if that be possible.

Having taken this preliminary objection to the form in which the proposal has been published, let us consider the proposal itself. As it is only a suggestion and the operation has never been performed we can only fall back upon *a priori* arguments. And we are all aware how fallacious such arguments are. How many of the great advances which have raised surgery to its present exalted position have been ruthlessly condemned on *a priori* grounds? The surgery of the brain, the stomach, the spleen, the liver, and the uterus has all been advanced and almost perfected in spite of weighty *a priori* reasons against the procedures which are now known to be useful. So that, as a general rule, we deprecate such a line of reasoning. Experiment and observation are the "weapons of our warfare," and the only ones in which we have much confidence. But Sir LAUDER BRUNTON'S proposal challenges criticism in two directions—the difficulty of the operation and the doubt as to its efficacy, even if successfully carried out. On a dead and motionless heart the division of the mitral valve through a fine puncture in the ventricle is a difficult and very delicate step. But when the operation is complicated by the rapid movements of the auricle and ventricle and the respiratory movements of the chest it is plain that the operation is beset with very grave difficulties—difficulties that only the boldest surgeons, with the best-balanced sense of the limitations of their science, could for a moment face. We think that these difficulties have been under-estimated and that the very technique of the operation will prove fatal to its adoption. The introduction of a fine knife through the ventricular wall would have to be done rapidly, and then the manipulation of the knife into the orifice between the deformed cusps of the mitral valve and the section of the valve would also have to be accomplished very rapidly; and all this in conditions most embarrassing and most destructive of that entire self-control which is the chief secret of success in rapid and exact surgical manœuvres. But were this difficulty overcome and the safety and feasibility of the operation established, a further doubt arises in our mind. If the narrowed valve is divided what hope is there that the incision in the ve will heal without renewing the contraction? e incision in such a valve would show a great tendency unite directly and the state of the valve would then be worse than before. It has been clearly established in the surgical treatment of stricture of the urethra or rectum that simple division of the contracted fibrous tissue is of little good unless it is followed up by the frequent passage of suitable instruments to keep the mucous canals quite free and open, and so to prevent the direct union of the edges of the wound. Now this cannot be done in the valvular orifices of the heart. If it is urged that the force with which the blood is driven through from the auricle is sufficient to keep open the passage, it must be replied that this force proved in the first place wholly inadequate to prevent the contraction of the valve, and, therefore, that there is little reason to hope that it would prove efficient in resisting a still stronger contracting force. It has also to be borne in mind that the operation might convert the valvular lesion from a mitral stenosis into a mitral regurgitation with very doubtful benefit to the patient. For the difficulties of the procedure must be enormous.

Should our anticipations of failure be proved to be groundless we shall indeed rejoice to witness an extension of surgery which might be attended with great alleviation of human suffering. But we can only repeat that the mere suggestion of surgical operation for the relief of mitral stenosis casts a grave responsibility upon Sir LAUDER BRUNTON, and a responsibility that he does not lessen by now leaving it to other workers to prove or to disprove its value.

"Ne quid nimis."

## CHANGES OF WEATHER AND TEMPERAMENT.

METEOROLOGICAL influences were recognised by the ancients, notably by the Egyptians and by Hippocrates. The latter in a series of aphorisms made some very definite observations on seasonal effects upon the human body, many of which are in perfect accord with modern experience. It cannot be gainsaid, for example, that changes of seasons and the alternation of cold and heat in those seasons are most effectual causes of disease. It is well known that some persons feel in better health in winter than in summer and *vice versâ*. Hippocrates pointed out that the south wind dulls the senses of hearing and sight, causes headache, heaviness, and faintness, and that the north wind affects the chest and throat. The south wind relaxes and the north wind contracts the tissues of the body. All these effects wrought by seasonal oscillations must have their influences over the great physiological processes. Nowadays we attribute more correctly such influences to changes of temperature, of pressure, and of the degree of humidity of the air—changes which are more in evidence at certain times of the year than at others They are, in fact, seasonal changes giving rise to seasonal symptoms. Hippocrates lived before means were found of measuring temperature and pressure; the thermometer was discovered in the sixteenth century and the barometer 100 years later. Hence his observations referred to cold and heat and to the direction of the winds. The effects of changes of temperature upon the body are better understood, perhaps, than those due to pressure. Yet that pressure must exert a marked influence upon the body and its functions is certain, since the weight sustained by an average body when the barometer is at a normal height is no less than 15 tons. Further, this pressure is constantly varying. Thus a rapid fall in the barometer may mean the withdrawal of a ton weight upon the body, and conversely a rapid rise in the barometer would mean saddling the body with an increased weight upon it to the extent of one ton. Such a change surely must affect the human disposition. There is no doubt that it does, and it is frequently manifested in disagreeable symptoms, discomfort, a want of feeling of well-being, a lack of geniality, and so on. The proverbial grumbling disposition of the Englishman may thus be the result of the successive generations in this island being exposed to all the types of weather which it is possible to experience. At any

rate, there is certainly a relationship between character and climate.

## SMALL-POX IN LONDON.

THE small-pox returns for the past week show the following figures. On Saturday, Feb. 8th, there were 32 fresh cases notified and removed; on Sunday, the 9th, there were 23 fresh cases; on Monday, the 10th, there were 48 fresh cases; on Tuesday, the 11th, there were 58 fresh cases; and on Wednesday, the 12th, there were 58 fresh cases. There are no less than 169 male and six female foreign physicians, surgeons, and general practitioners located in London. Of these, there are nine male and one female who are Russians; one male Russian Pole; seven male, three female, Swedes; two male Norwegians; three male Danes; four male Dutch; one male Belgian; 12 male French; 32 male, one female, Germans; three male Austrians; eight male Swiss; three male Spaniards; one male Portuguese; 12 male, one female, Italians; two male Greeks; three male Turks; two male Japanese; one male Asiatic; and 63 male Americans. 16,107 persons living in London are returned as "sick nurses, invalid attendants," of whom 15,844 are females; three of the latter are stated to be blind. 268 "midwives" are also returned in London. There are 62 female dentists in London.

## POISONING BY CUTANEOUS ABSORPTION OF ANILINE.

IN the December number of the *Archives Générales de Médecine* Dr. Georges Brouardel of Paris has collected particulars of several cases of poisoning due to the wearing of boots to which a black material containing aniline had been recently applied. The patients were mostly children from the age of 17 months upwards, but at least two of them were adult males. The attacks occurred during hot or moderately warm weather. Attention was first called to this particular form of aniline poisoning by Dr. Landouzy and Dr. Brouardel, who brought it before the Paris Academy of Medicine in July, 1900. The boots seem to have been in all cases of yellow leather, the colour of which was changed to black either because they had become shabby or because the wearers happened to be in mourning. The symptoms were quite similar to those which have from time to time been presented by workers in aniline factories and usually appeared in from one hour to three or four hours after the boots were put on. Generally, before the patients felt themselves ill their paleness and the remarkable blueness of their lips and fingers had attracted the attention of those in their company; this stage was soon followed by giddiness, shivering, increased cyanosis, muscular relaxation, and loss of consciousness, either partial or complete. In severe cases this condition persisted for about 24 hours, but in mild cases for only a short time. No deaths occurred. The boots

and skill on the part of the experimenter, and we have a strong feeling that the man with whom the idea originated is certainly the most fitted to cope with the initial difficulties and to bring the experiments to a satisfactory conclusion, if that be possible.

Having taken this preliminary objection to the form in which the proposal has been published, let us consider the proposal itself. As it is only a suggestion and the operation has never been performed we can only fall back upon *a priori* arguments. And we are all aware how fallacious such arguments are. How many of the great advances which have raised surgery to its present exalted position have been ruthlessly condemned on *a priori* grounds? The surgery of the brain, the stomach, the spleen, the liver, and the uterus has all been advanced and almost perfected in spite of weighty *a priori* reasons against the procedures which are now known to be useful. So that, as a general rule, we deprecate such a line of reasoning. Experiment and observation are the "weapons of our warfare," and the only ones in which we have much confidence. But Sir LAUDER BRUNTON'S proposal challenges criticism in two directions—the difficulty of the operation and the doubt as to its efficacy, even if successfully carried out. On a dead and motionless heart the division of the mitral valve through a fine puncture in the ventricle is a difficult and very delicate step. But when the operation is complicated by the rapid movements of the auricle and ventricle and the respiratory movements of the chest it is plain that the operation is beset with very grave difficulties—difficulties that only the boldest surgeons, with the best-balanced sense of the limitations of their science, could for a moment face. We think that these difficulties have been under-estimated and that the very technique of the operation will prove fatal to its adoption. The introduction of a fine knife through the ventricular wall would have to be done rapidly, and then the manipulation of the knife into the orifice between the deformed cusps of the mitral valve and the section of the valve would also have to be accomplished very rapidly; and all this in conditions most embarrassing and most destructive of that entire self-control which is the chief secret of success in rapid and exact surgical manœuvres. But were this difficulty overcome and the safety and feasibility of the operation established, a further doubt arises in our mind. If the narrowed valve is divided what hope is there that the incision in the valve will heal without renewing the contraction? The incision in such a valve would show a great tendency to unite directly and the state of the valve would then be worse than before. It has been clearly established in the surgical treatment of stricture of the urethra or rectum that simple division of the contracted fibrous tissue is of little good unless it is followed up by the frequent passage of suitable instruments to keep the mucous canals quite free and open, and so to prevent the direct union of the edges of the wound. Now this cannot be done in the valvular orifices of the heart. If it is urged that the force with which the blood is driven through from the auricle is sufficient to keep open the passage, it must be replied that this force proved in the first place, wholly inadequate to prevent the contraction of the valve, and, therefore, that there is little reason to hope that it would prove efficient in resisting a still stronger contracting force. It has also to be borne in mind that the operation might convert the valvular lesion from a mitral stenosis into a mitral regurgitation with very doubtful benefit to the patient. For the difficulties of the procedure must be enormous.

Should our anticipations of failure be proved to be groundless we shall indeed rejoice to witness an extension of surgery which might be attended with great alleviation of human suffering. But we can only repeat that the mere suggestion of surgical operation for the relief of mitral stenosis casts a grave responsibility upon Sir LAUDER BRUNTON, and a responsibility that he does not lessen by now leaving it to other workers to prove or to disprove its value.

## CHANGES OF WEATHER AND TEMPERAMENT.

METEOROLOGICAL influences were recognised by the ancients, notably by the Egyptians and by Hippocrates. The latter in a series of aphorisms made some very definite observations on seasonal effects upon the human body, many of which are in perfect accord with modern experience. It cannot be gainsaid, for example, that changes of seasons and the alternation of cold and heat in those seasons are most effectual causes of disease. It is well known that some persons feel in better health in winter than in summer and *vice versâ*. Hippocrates pointed out that the south wind dulls the senses of hearing and sight, causes headache, heaviness, and faintness, and that the north wind affects the chest and throat. The south wind relaxes and the north wind contracts the tissues of the body. All these effects wrought by seasonal oscillations must have their influences over the great physiological processes. Nowadays we attribute more correctly such influences to changes of temperature, of pressure, and of the degree of humidity of the air—changes which are more in evidence at certain times of the year than at others. They are, in fact, seasonal changes giving rise to seasonal symptoms. Hippocrates lived before means were found of measuring temperature and pressure; the thermometer was discovered in the sixteenth century and the barometer 100 years later. Hence his observations referred to cold and heat and to the direction of the winds. The effects of changes of temperature upon the body are better understood, perhaps, than those due to pressure. Yet that pressure must exert a marked influence upon the body and its functions is certain, since the weight sustained by an average body when the barometer is at a normal height is no less than 15 tons. Further, this pressure is constantly varying. Thus a rapid fall in the barometer may mean the withdrawal of a ton weight upon the body, and conversely a rapid rise in the barometer would mean saddling the body with an increased weight upon it to the extent of one ton. Such a change surely must affect the human disposition. There is no doubt that it does, and it is frequently manifested in disagreeable symptoms, discomfort, a want of feeling of well-being, a lack of geniality, and so on. The proverbial grumbling disposition of the Englishman may thus be the result of the successive generations in this island being exposed to all the types of weather which it is possible to experience. At any

rate, there is certainly a relationship between character and climate.

## SMALL-POX IN LONDON.

THE small-pox returns for the past week show the following figures. On Saturday, Feb. 8th, there were 32 fresh cases notified and removed; on Sunday, the 9th, there were 23 fresh cases; on Monday, the 10th, there were 48 fresh cases; on Tuesday, the 11th, there were 58 fresh cases; and on Wednesday, the 12th, there were 58 fresh cases. With regard to the question to which we referred last week of the vaccination or revaccination of the employés of large firms, Messrs Bradbury and Wilkinson in a letter to the *Times* of the 10th, stated that although they had made arrangements for offering vaccination to their employés, the operation could not be carried out because the public vaccinator was unable to vaccinate any person living outside his own district. Messrs. Octavius H. Smith and Co., in a letter to the *Times* of the 11th, also stated that the public vaccinator for their district pointed out this difficulty. Messrs. Smith, however, thereupon wrote to the Local Government Board who granted the public vaccinator special leave to vaccinate any of Messrs. Smith's employés although they did not reside in his district.

## THE METROPOLITAN WATER-SUPPLY.

THE report on the condition of the metropolitan water-supply during the month of December, 1901, has recently been issued by the Local Government Board. The Water Examiner states that the water of the Thames was in good condition at Hampton, Molesey, and Sunbury from the 1st to the 12th and from the 19th to the 24th days of the month under review. The engineer to the Chelsea Waterworks Company reports that on the 13th, 18th, and 25th days of the month the water at West Molesey was of "indifferent" character, and that from the 14th to the 17th and from the 26th to the 31st the state of the water was "bad." During the whole of the period at which the water was bad the intake of the Chelsea Company was closed. In the case of the Southwark and Vauxhall Company the river intake to the filters at Hampton was open from the 1st to the 30th of the month. On Dec. 30th Dr. T. E. Thorpe, the analyst to the Local Government Board, found that taking the average amount of organic impurity in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, the proportional amount in an equal volume of the Southwark Company's water amounted to no less than 3·6. On the same day the water supplied by the Lambeth Company showed an even greater amount of organic impurity (5·3) as judged by the same standard, but the worst water of all was that supplied by the Grand Junction Company on Dec. 31st, which gave a comparative result represented by the figures 5·4. On Dec. 30th the Lambeth Company's water was very faintly opalescent. The Thames at its highest point during the month was one foot three inches above, and at its lowest one foot below, the average summer level. The rainfall during the month at West Molesey was 3·05 inches. The average total daily amount of water distributed by the companies was 197,577,154 gallons for a population estimated at 6,307,230, and this represents a daily consumption per head of 31·33 gallons for all purposes. The company which is stated to supply the largest daily amount per head is the Grand Junction, and the one which supplies the smallest amount is the East London, the figures given being respectively 42·06 gallons and 25·87 gallons. With the exception of the Lambeth Company all the metropolitan companies supplied less water per head during the month than that given in December, 1900 The companies which now profess to give a constant water-service to their customers are the Chelsea, the East London, the Grand Junction, and the West Middlesex. Of the other companies the Kent, the New River, and the Southwark and Vauxhall supply respectively 95·9, 95·7, and 93·0 per cent., as compared with 92·3, 95·0, and 93·2 per cent. in December, 1900. The Lambeth Company professes to give constant service to no more than 77·5 per cent. of its customers. The proportions of brown tint observed in a two-foot tube varied very greatly in the different samples examined; it ranged from two to 30 degrees of the standard in use. The brown tint which is due to the presence of foreign matter or dirt is well marked in the water supplied by those companies which have a deficient storage capacity or an insufficient filtration area at those periods at which turbid water is taken from the Thames for immediate use. The water of the Lambeth Company exhibited the deepest average tint of brown. Dr. Thorpe says of a specimen of the Southwark Company's water that it "was good for the time of year"—a statement which seems to require elucidation. All the samples taken of the water supplied by the Kent Company were of their usual excellent quality

## FOREIGN MEDICAL PRACTITIONERS IN LONDON: SOME INTERESTING FIGURES.

ACCORDING to the recently issued census returns there are 4801 "physicians, surgeons, and general practitioners" in London, of whom 92 are females. There are no less than 169 male and six female foreign physicians, surgeons, and general practitioners located in London. Of these, there are nine male and one female who are Russians; one male Russian Pole; seven male, three female, Swedes; two male Norwegians; three male Danes; four male Dutch; one male Belgian; 12 male French; 32 male, one female, Germans; three male Austrians; eight male Swiss; three male Spaniards; one male Portuguese; 12 male, one female, Italians; two male Greeks; three male Turks; two male Japanese; one male Asiatic; and 63 male Americans. 16,107 persons living in London are returned as "sick nurses, invalid attendants," of whom 15,844 are females; three of the latter are stated to be blind. 266 "midwives" are also returned in London. There are 62 female dentists in London

## POISONING BY CUTANEOUS ABSORPTION OF ANILINE.

IN the December number of the *Archives Générales de Médecine* Dr. Georges Brouardel of Paris has collected particulars of several cases of poisoning due to the wearing of boots to which a black material containing aniline had been recently applied. The patients were mostly children from the age of 17 months upwards, but at least two of them were adult males. The attacks occurred during hot or moderately warm weather. Attention was first called to this particular form of aniline poisoning by Dr. Landouzy and Dr. Brouardel, who brought it before the Paris Academy of Medicine in July, 1900. The boots seem to have been in all cases of yellow leather, the colour of which was changed to black either because they had become shabby or because the wearers happened to be in mourning. The symptoms were quite similar to those which have from time to time been presented by workers in aniline factories and usually appeared in from one hour to three or four hours after the boots were put on. Generally, before the patients felt themselves ill their paleness and the remarkable blueness of their lips and fingers had attracted the attention of those in their company; this stage was soon followed by giddiness, shivering, increased cyanosis, muscular relaxation, and loss of consciousness, either partial or complete. In severe cases this condition persisted for about 24 hours, but in mild cases for only a short time. No deaths occurred. The boots

and skill on the part of the experimenter, and we have a strong feeling that the man with whom the idea originated is certainly the most fitted to cope with the initial difficulties and to bring the experiments to a satisfactory conclusion, if that be possible.

Having taken this preliminary objection to the form in which the proposal has been published, let us consider the proposal itself. As it is only a suggestion and the operation has never been performed we can only fall back upon *a priori* arguments. And we are all aware how fallacious such arguments are. How many of the great advances which have raised surgery to its present exalted position have been ruthlessly condemned on *a priori* grounds? The surgery of the brain, the stomach, the spleen, the liver, and the uterus has all been advanced and almost perfected in spite of weighty *a priori* reasons against the procedures which are now known to be useful. So that, as a general rule, we deprecate such a line of reasoning. Experiment and observation are the "weapons of our warfare," and the only ones in which we have much confidence. But Sir LAUDER BRUNTON'S proposal challenges criticism in two directions—the difficulty of the operation and the doubt as to its efficacy, even if successfully carried out. On a dead and motionless heart the division of the mitral valve through a fine puncture in the ventricle is a difficult and very delicate step. But when the operation is complicated by the rapid movements of the auricle and ventricle and the respiratory movements of the chest it is plain that the operation is beset with very grave difficulties—difficulties that only the boldest surgeons, with the best-balanced sense of the limitations of their science, could for a moment face. We think that these difficulties have been under-estimated and that the very technique of the operation will prove fatal to its adoption. The introduction of a fine knife through the ventricular wall would have to be done rapidly, and then the manipulation of the knife into the orifice between the deformed cusps of the mitral valve and the section of the valve would also have to be accomplished very rapidly; and all this in conditions most embarrassing and most destructive of that entire self-control which is the chief secret of success in rapid and exact surgical manœuvres. But were this difficulty overcome and the safety and feasibility of the operation established, a further doubt arises in our mind. If the narrowed valve is divided what hope is there that the incision in the valve will heal without renewing the contraction? The incision in such a valve would show a great tendency to unite directly and the state of the valve would then be worse than before. It has been clearly established in the surgical treatment of stricture of the urethra or rectum that simple division of the contracted fibrous tissue is of little good unless it is followed up by the frequent passage of suitable instruments to keep the mucous canals quite free and open, and so to prevent the direct union of the edges of the wound. Now this cannot be done in the valvular orifices of the heart. If it is urged that the force with which the blood is driven through from the auricle is sufficient to keep open the passage, it must be replied that this force proved in the first place wholly inadequate to prevent the contraction of the valve, and, therefore, that there is little reason to hope that it would prove efficient in resisting a still stronger contracting force. It has also to be borne in mind that the operation might convert the valvular lesion from a mitral stenosis into a mitral regurgitation with very doubtful benefit to the patient. For the difficulties of the procedure must be enormous.

Should our anticipations of failure be proved to be groundless we shall indeed rejoice to witness an extension of surgery which might be attended with great alleviation of human suffering. But we can only repeat that the mere suggestion of surgical operation for the relief of mitral stenosis casts a grave responsibility upon Sir LAUDER BRUNTON, and a responsibility that he does not lessen by now leaving it to other workers to prove or to disprove its value.

## CHANGES OF WEATHER AND TEMPERAMENT.

METEOROLOGICAL influences were recognised by the ancients, notably by the Egyptians and by Hippocrates. The latter in a series of aphorisms made some very definite observations on seasonal effects upon the human body, many of which are in perfect accord with modern experience. It cannot be gainsaid, for example, that changes of seasons and the alternation of cold and heat in those seasons are most effectual causes of disease. It is well known that some persons feel in better health in winter than in summer and *vice versâ*. Hippocrates pointed out that the south wind dulls the senses of hearing and sight, causes headache, heaviness, and faintness, and that the north wind affects the chest and throat. The south wind relaxes and the north wind contracts the tissues of the body. All these effects wrought by seasonal oscillations must have their influences over the great physiological processes. Nowadays we attribute more correctly such influences to changes of temperature, of pressure, and of the degree of humidity of the air—changes which are more in evidence at certain times of the year than at others They are, in fact, seasonal changes giving rise to seasonal symptoms. Hippocrates lived before means were found of measuring temperature and pressure; the thermometer was discovered in the sixteenth century and the barometer 100 years later. Hence his observations referred to cold and heat and to the direction of the winds. The effects of changes of temperature upon the body are better understood, perhaps, than those due to pressure. Yet that pressure must exert a marked influence upon the body and its functions is certain, since the weight sustained by an average body when the barometer is at a normal height is no less than 15 tons. Further, this pressure is constantly varying. Thus a rapid fall in the barometer may mean the withdrawal of a ton weight upon the body, and conversely a rapid rise in the barometer would mean saddling the body with an increased weight upon it to the extent of one ton. Such a change surely must affect the human disposition. There is no doubt that it does, and it is frequently manifested in disagreeable symptoms, discomfort, a want of feeling of well-being, a lack of geniality, and so on. The proverbial grumbling disposition of the Englishman may thus be the result of the successive generations in this island being exposed to all the types of weather which it is possible to experience. At any tinge—was present; the pulse was 130. These symptoms persisted for a week and then gradually disappeared. On the sixtieth day there was no fever and the general condition was good. Three weeks after defervescence the patient got up, but the abdominal pain and tympanites at once reappeared, the evening temperature rose to 100·4° F., and a tumour was found in the right iliac fossa. Appendicitis was suspected and laparotomy was performed. A large ovarian cyst containing 1500 grammes of blackish fluid which yielded the typhoid bacillus in pure culture was found. The patient's blood had still a high agglutinative power. The cyst and the right Fallopian tube were removed and rapid recovery ensued.

## LAPSES OF MEMORY IN RAILWAY EMPLOYÉS.

IN the course of a discussion at a meeting of American railway surgeons held in Chicago and recently reported in the *Railway Surgeon*, Dr. A. F. Jonas of Omaha, Nebraska, said that as with many other persons so with railroad men there was now and then a mental blank when a man did not think or his mind did not operate. This was the only explanation for the fact that some men ran into an obstruction in broad daylight when it was plainly visible. He then quoted an instance of this kind. Dr. A. T. Eskridge of Denver, Colorado, the next speaker, said that these cases of amnesia were of not infrequent occurrence on railroads and were usually due to definite causes. The greatest cause was alcoholism, not in the sense of drunkenness at the time, but of drunkenness a day or two before. The brain was then in an automatic state in which it could not adapt itself to new conditions. Dr. D. S. Fairchild of Clinton, Iowa, the president of the meeting, said that the observations made by Dr. Eskridge struck him very forcibly and in his opinion accounted satisfactorily for certain inexplicable accidents. He then related a case in which through a switch being turned the wrong way one of the most important trains on a certain railway left the main line and went off on a branch line. The main line was a double track and crossed a bridge, and the branch line was single and passed through a cutting, but the engine was allowed to run for eight miles before the driver discovered his mistake. Fortunately, no accident occurred. The driver when off duty drank freely and occasionally got drunk, but he was always sober when he went on the engine.

## SMALL-POX AND ISOLATION.

AS we surmised the statements made about the Small-pox Hospital at South Mimms before the Barnet Rural District Council on Jan. 23rd were in some cases exaggerated and in others apparently simply untrue. It appears that the same statements have been made previously by various people, and the secretary of the hospital has forwarded to us letters and copies of his answers which deal with the points upon which we commented. From these documents and letters we learn: 1. That *the staff all* reside on the premises, with one exception only. She resides at Clare Hall, *an old house in the grounds*. She never goes to the hospital, and always changes her clothes and has a disinfectant bath before leaving. 2. As to convalescents leaving the grounds and going to the public-house this has not occurred What did happen was that some patients after discharge went to the public-house. 3. With regard to convalescents and the fence, the fence on the east side is an oak one more than six feet high. Convalescent patients are only allowed *in certain parts of* the ground and an unclimbable iron fence is being erected to keep them away from the highway altogether. A further fence is being erected on the northern side which will be five feet six inches high. When this fence is erected there will be a double barrier. 4. As to the workmen, neither the hospital authorities nor anyone else can compel workmen to be vaccinated or to remain within the hospital grounds. Notices are, however, posted forbidding them to have any communication with the convalescents and offering to vaccinate them gratuitously and to disinfect their clothing. Contractors are now requested to get their workmen to comply with these conditions. So far, then, as we can see the statements upon which we commented seem to be, if not without foundation, grossly exaggerated, with the single exception that possibly convalescents may have been able to approach too near to the highway A small-pox hospital is, of course, a necessary evil, but we earnestly advise all the dwellers in the neighbourhood to get vaccinated without delay. They will then be practically free from all danger; and it is only fair that if the hospital authorities take precautions the local inhabitants should do so too.

## CALEDONIAN MEDICAL SOCIETY.

THE awards of the Gunning Celtic prizes offered by the Caledonian Medical Society for original work on Medico-Celtic subjects have just been made public. The adjudicators, Principal Rhys of Oxford and Professor Mackinnon of Edinburgh, have awarded the first prize of £20 to Dr. H. Cameron Gillies of Hampstead for his paper on a Gaelic Medical MS. of 1563. This manuscript, which the author discovered in the British Museum, belonged to the famous Beaton family who were hereditary physicians to the Kings of Scotland from the beginning of the fourteenth century. The second prize of £10 has been awarded to Mrs. K. Whyte Grant, New Zealand, for an essay on the Influence of Scenery and Climate on the Poetry and Music of the Highlands. The papers will be published in the *Caledonian Medical Journal*.

## THE STEREOTYPED ATTITUDES AND POSTURES OF THE INSANE IN REGARD TO DIAGNOSIS AND PROGNOSIS.

DR. ALBERT CAHEN has contributed to the December number of *Archives de Neurologie* a minute study of the "stereotyped attitudes and postures" characteristic of many forms of insanity, a subject to which much popular clinical interest has been accorded, but which has been little studied as regards diagnostic and prognostic value At the outset such conditions as *tics*, spasms, choreiform movements, and impulsive acts were excluded from the present research, which was limited to stereotyped movements and attitudes in the strict sense—i.e , such as were marked by automatism, long duration and persistence of attitude, and by being repeated frequently and in the same way. Such acts were, moreover, stamped by a "professional" appearance in some cases and had the semblance of being voluntary and intentional. They included attitudes, peculiarities of language, gestures, and modes of walking. The following were illustrative instances attitudes of crouching like a beast without moving, standing or sitting in fixed poses which had an insane or delusional significance, automatic buttoning and unbuttoning of the clothes, modes of stamping the floor and of walking a few paces forwards and then backwards, lispings and utterings of sounds and words which the patient held to have a spiritual or mystic meaning (neologisms), and mutism When a patient exhibiting any of the above peculiarities was examined at the onset of his illness inquiry generally revealed that the cause of his actions was a delusion of grandiose, mystic, hypochondriacal, or persecutory nature, provoking reactions and attitudes of a defensive character—*the attitudes, acts,* and postures in question. The patient who acted thus in the early stages of his disorder acted consciously, but later, owing to repetition, the reaction became automatic and stereotyped and the delusion became fixed and organised in the brain, so that the circuit which caused the mischief were said to smell like Indian or China ink; they were blackened with a composition containing a large proportion (90 per cent.) of ordinary aniline, which served as a vehicle for the black colouring agent. Dr. Landouzy and Dr. Brouardel found that aniline applied to the shaved skin of guinea-pigs and rabbits kept in a warm place produced illness in from three to four hours and death in from 24 to 36 hours.

## "CHRISTIAN SCIENCE" IN GERMANY.

THE German Emperor is stated to have no intention of allowing the mischievous and crack-brained disciples of Mrs. Eddy to have an opportunity of spreading their doctrines in the Fatherland. It will be interesting to see what steps the German authorities will be able to take in the matter, for while it is the duty of a Government to watch over the health of the people it cannot possibly be the province of any Government to decide what is and what is not correct medical treatment. It may be said that such a manifest absurdity as the theory of Christian science cannot possibly pretend to be a system of therapeutics; but, unfortunately, that is just what it does pretend to be. The German Emperor will earn the gratitude of English and American legislators if he can devise a plan which will stop these silly persons from playing with the lives of their fellow-creatures and which will at the same time give no chance to refractory persons to say that the freedom of the individual is being unduly curtailed.

## A BILL FOR THE BETTER PROTECTION OF CHILDREN.

WE are informed that a Bill to amend the Act for the Prevention of Cruelty to Children will shortly be introduced into the House of Lords. It proposes to restrict the working hours of children employed in domestic work and to prevent their being brought up as tramps. It would also make it illegal to endanger the lives of young children by overlying, by leaving them alone in rooms with an unprotected fire, and by having them carried about by drunken persons, and would seek to protect their moral character by prohibiting promiscuous sleeping arrangements. It may be said that much of the ground occupied by these amendments is covered by the general term "neglect" for which provision is made by the original Act. There can be no reasonable doubt that such is the case with regard to many so-called accidents due to burning and to overlying. Nor is the case of a child committed to the arms of an incapable drunkard essentially different. It is from our point of view hardly conceivable that a magistrate should be able under these circumstances to interpret the implied neglect as other than a punishable offence. Nevertheless, we should be most unwilling to lose any force derivable from detailed and exact definition which may be needful to strengthen the hands of magistrates in dealing with such occurrences. As regards the regulation of domestic arrangements we are of opinion that makers of law should walk warily. Questions arising in this connexion are best settled out of court as far as may be possible. When there is proof of oppression, or cruelty, or a public nuisance, we naturally look to the law for justice and reparation. Where we have to do with errors of judgment in respect of such matters as household occupations or decency we cannot shut our eyes to the help which can be derived from education or from the more delicate, subtle, and powerful influence of religion. It will be for those who have to discuss and to vote upon this Bill to say how far the evils with which it deals are real and how much they are to allow to one or the other or to all of these forces in seeking their removal. There is a related subject which we greatly desire to see taken up by the legislature with more energy than it has been—that of infant insurance. The history of this system as it is read by the critical onlooker is marked by a degree of mortality which is, at least, suggestive of widely prevalent abuse. Here, if anywhere, we would say, is a point at which legislation should intervene in a manner that it has not done. We have never been able to understand what pecuniary interest a poor parent can be considered to possess in the death of his young child apart from the cost of burial expenses. As a matter of fact, the sum insured is often far in excess of this moderate sum, so far that it bears a dangerous likeness to a premium on mortality. It is to be feared that it is not infrequently so regarded by parents who have more children than they care for and that a child's life has repeatedly gone in exchange for the insurance money. We believe that the necessity for this kind of insurance even among the poor has been overestimated. We are of opinion that it would be fairer to the child, fairer to the parents, and of greater public benefit, that instead of insurance being made for a payment of money it should be limited to providing decent burial in the event of death.

## LOCALISATION OF THE BACILLUS TYPHOID AT THE SITES OF INJURIES DURING RECEIVED TYPHOID FEVER AND AT THE SITES OF PREVIOUSLY EXISTING LESIONS.

WE have recently referred to the fact that typhoid bacilli are usually present in the blood in cases of typhoid fever and to the value of examination of the blood for them as a means of early diagnosis.[1] Some cases described at the meetings of the Société Médicale des Hôpitaux of Paris illustrate the ubiquity of the bacilli in cases of typhoid fever in a novel and interesting manner. At the meeting on Jan. 17th M. F. Widal and M. L. Le Sourd jointly described the case of a young woman, aged 24 years, in whom during convalescence from a long attack of typhoid fever an abscess and three "oily" subcutaneous collections developed in the positions of punctures made in injecting hypodermically caffeine and normal saline solution. In the pus of the abscess which was beneath the skin of the abdomen and in the oily collections which were situated on the left thigh the typhoid bacillus was found. This fact is analogous to the observation of several writers who have found pneumococcic abscesses at the sites at which subcutaneous injections of caffeine had been made in cases of pneumonia. In the abscess the typhoid bacillus and the staphylococcus aureus were found. In the oily collections the typhoid bacillus was found in pure culture. Histological examination showed polynuclear cells mixed with some lymphocytes. In this case the slight injury produced by the needle of the hypodermic syringe evidently localised the typhoid bacillus which must have been present in the blood. At the meeting of the Société Médicale des Hôpitaux on Jan. 24th M. Widal and M. Ravaut gave examples of the localisation of the typhoid bacillus in the sites of lesions existing before the occurrence of the typhoid fever. A young woman had chronic submaxillary tuberculous adenitis. During convalescence from typhoid fever one of the tuberculous glands enlarged and became red and fluctuating. On incision pus was obtained containing the typhoid bacillus in pure culture. Cicatrisation rapidly occurred. A woman, aged 34 years, had typical typhoid fever which ran the ordinary course until the twentieth day, but there was abdominal pain, especially on the right side. On the twenty-first day vomiting occurred and the abdomen became tympanitic and more painful. The febrile symptoms persisted for three weeks. At the end of this time the abdominal pains returned in a violent form, greenish matter was vomited, and the abdominal facies—pinched nose, hollow eyes, and leaden out, should go a long way towards effecting a changed condition of things. Obviously no pains should be spared to encourage medical officers in their purely professional work and, as far as possible, to enable them to maintain a high order of scientific merit. There is, too, the question of what should be done in future wars in regard to everything appertaining to practical field sanitation and the organisation of a sanitary corps. This is a subject which we have already fully discussed in the series of articles that appeared in THE LANCET during the past year and we were very glad to see that it did not escape the attention of Professor A. Ogston who gave it the first place in his addendum to the report of Mr. Brodrick's Committee. The approval and coöperation of the Indian Government in the new warrant will, of course, have to be secured seeing that so large a number of officers of the Royal Army Medical Corps are employed with the British troops serving in India.

---

[1] THE LANCET, Feb. 8th, 1901, p. 390

## THE DISTRIBUTION OF PLAGUE.

DURING the week ending Feb. 2nd 22 cases of plague and 16 deaths from the disease have been reported throughout Egypt. 18 cases and 14 deaths occurred at Tantah, 9 of the latter occurring out of hospital; 1 Greek died from the disease in hospital; the remainder of the cases and deaths occurred among the native population. 5 cases and 4 deaths occurred in one house, 2 cases in another, and 1 case in a third at Tantah where cases had a few days previously been found after death; this points to the great necessity of the people at once notifying all cases of sickness to the sanitary authorities, as in all probability if the first cases of plague had been at once isolated and properly treated no further cases would have occurred in the same houses. 2 cases and 1 death were announced from Abousir in the Mehalla district of Gharbieh, 1 death out of hospital at the village of Kafr Euan near to Zifteh, and 1 case in the village of Koum-El-Nour near to Mit Ghamr. All these cases were from among the native population.

## DECLARED ADULTERATION NO OFFENCE.

As is well known practically the Food and Drugs Act can be evaded by the seller adopting the expedient of declaring the adulteration of the article that he sells. This practice of declaration is steadily extending and is threatening to reduce the Act to a dead letter. At one time it was only the publican who announced in his shop that in order to comply with the requirements (*sic*) of the Food and Drugs Act the articles which he sold were diluted. Now some grocers on a similar principle post a notice to the effect that the butter which they sell contains a certain proportion of milk—the addition of milk amounts to the butter being watered—and many restaurant proprietors, and especially those who cater at railway-stations, intimate to the public that they cannot guarantee to supply milk with its full complement of cream. It may be noted that the railway restaurant is often the traveller's only opportunity of obtaining food and drink, and yet by this system of notification he has no means of securing genuine articles. Something ought to be done to stop this practice which, if it grows as it appears to be doing, is calculated to defeat the objects of the Act—namely, to maintain the quality of the food-supply. No legislation which aims at a high standard of food-supply can be too strict. Yet legislation in the instances which we have quoted is admittedly defeated—a most deplorable state of things. An expedient that protects the seller and not the consumer is opposed to sound principles. It is difficult to suggest how this practice can be effectually checked unless the law is made to demand the sale of foods strictly in accordance with a prescribed standard. It should, at any rate, be insisted upon that when the adulteration of an article of food is declared it should be done in the plainest possible terms. The statements should be strongly positive, and not negative, intimating what is sold and not what is not sold. The publican should state, "I sell watered spirits"; the grocer, "I sell watered butter" or "I sell starch glucose and not golden syrup"; and the restaurant proprietor, "I sell skimmed milk." It might be possible to base legislative action on the price charged for such watered goods. There is a wide difference between the price of water and that of genuine butter or milk, or that of undiluted brandy, gin, or whisky.

## CRIME IN ITS FUTURE DEVELOPMENTS.

IN a brief summary of the progress and future of crime in European countries and in America from the pen of Professor Lombroso which appeared in the *Medical News* of New York of Jan. 11th the following main conclusions are arrived at. Assassination has diminished by one-half and so has incendiarism during the latter half of the nineteenth century. A certain group of crimes of blood and theft still remain, because the degeneration which accompanies, or is favoured by, civilisation, although it finds an outlet in suicide and insanity, will always furnish a quota, however scarce, of crimes. In England a survey of judicial and criminal statistics shows that habitual criminals have increased during the period from 1863 to 1898 by about 10 per cent. over and above the rate of increase of population, and this statement does not include suicides and epileptic criminals. Suicide has increased to an appalling extent in the most civilised countries, while crimes committed by epileptics seem to show a considerable increase. "In conclusion," says Professor Lombroso, "it appears probable that crime will not wholly disappear in the world, no matter what cure we may apply to it, though most crimes will decrease in brutality and in number with the exception of those against woman." In time to come civilised man will consider crime as a strange and monstrous product to be regarded with compassion mixed with abhorrence and disgust. The outlook for the future as regards the progress of crime is thus not altogether pessimistic, for it is evident from Professor Lombroso's observations that on the whole the tendency is for a diminution in the frequency and brutality of crime with the progress of time.

## CLINICAL INSTRUCTION IN SMALL-POX.

AT the meeting of the Metropolitan Asylums Board held on Feb. 8th the Hospitals Committee submitted draft regulations relative to clinical instruction in small-pox, together with a recommendation that the Local Government Board should be requested to modify the terms of its Order of Oct. 30th, 1893, so as to remove the obligation of residence at present imposed on students at the small-pox hospitals and to enable qualified medical men to attend special demonstrations to be given from time to time thereat. The principal points of the draft regulations are as follows: (1) no student shall be admitted to study at the hospital until he has completed the third year of his medical education, has held the offices of clinical clerk and dresser, and has obtained from his medical school sanction to his attendance at the hospital; (2) the ordinary course of study at the hospital shall consist of 12 demonstrations and no student shall receive a certificate who has not attended at eight of them; (3) the fee shall be four guineas; (4) the means of conveyance to and from the small-pox hospitals shall be by the Board's steamboats to and from its London wharf; (5) every student will be required to wear, as long from mental delusion to motor reaction was organically complete. Such stereotyped acts were present in cases of dementia præcox, catatonia, dementia secondary to the maniacal-melancholic group of insanities, paranoia, *délire de négation*, and secondary mental enfeeblement generally, and hence they might also be observed in the early and middle stages of general paralysis. The insanity of obsessions (morbid doubts and fears) might also provoke characteristic attitudes of passion, doubt, religiosity, and fear which from recurrence might become fixed and stereotyped. Dr. Cahen points out that it is sometimes difficult to distinguish the stereotyped attitudes and actions of the insane from those which occur in hystero-epilepsy and hysteria major, but that such phenomena were of bad prognosis as being indicative of a permanent degree of mental enfeeblement—that is to say, of chronicity and incurability as regards the mental life. The prognosis, however, as regards bodily life need not be, and often was not, grave.

## THE UNQUALIFIED ASSISTANT ON HIS OWN ACCOUNT.

THE unqualified assistant of the medical practitioner is now limited in his duties by the General Medical Council. How great a source of danger to the public he is when he begins to consider himself competent to do a little in the way of unqualified practice on his own account we all know. A good example of this kind of unqualified practice was brought to light the other day by an inquest at Hackney. The deceased had been attended for 18 months by a person whom her husband knew as "Dr." Edwards, but who apparently had been dispenser to one or two medical men practising in the district. Edwards seems to have begun by treating the family of his lodging-house keeper for small ailments, and, being recommended by them or others, to have come to treat the deceased woman as to whose death the inquiry was held. He was paid for his attendance upon her; a bottle was produced which was said to have contained medicine prescribed by him, but which bore no label or directions. The husband had no knowledge that Edwards was not a fully qualified practitioner. Evidence was given that the patient died from syncope due to fatty degeneration of the heart, and a verdict of "Death from natural causes" was returned, accompanied by a rider censuring Edwards. Edwards, it would seem, is not in any way amenable to the law, for the law does not forbid unqualified practice. When a patient dies under the care of an unqualified person, and the affair becomes known, because the unqualified person cannot give a certificate, the public awake to the danger. But in a very short time vigilance relapses and the unqualified practitioner continues his dangerous career.

## SUSPECTED POISONING BY ARSENIC IN BEER AT HALIFAX.

IN our issue of Feb. 8th (p. 385) we referred in a leading article to an inquest held upon the body of an old man who died from cardiac failure and bronchitis. There is, of course, nothing remarkable about these two causes of death, but on his admission to the Halifax Workhouse Hospital the patient showed marked symptoms of arsenical poisoning such as were observed during the recent outbreak at Manchester. Dr. J. F. Hodgson, the resident medical officer, therefore reported the case so that an inquest might be held. On Feb. 7th another inquest was held by Mr. E. H. Hills upon the body of a man named Thomas Lee, aged 54 years, who died on Feb. 5th in the Halifax Workhouse Hospital. Evidence was given that Lee during life was a heavy drinker. He would drink "rum, whiskey, ale, or anything." Mr. J. F. Woodyatt, visiting physician to the hospital, gave evidence that Lee on admission presented all the symptoms of so-called arsenical beer-poisoning. The cause of death was croupous pneumonia. While under treatment Lee eliminated arsenic daily. He also had old pleurisy and morbus cordis. Dr. Hodgson confirmed Mr. Woodyatt's statements as to the arsenical poisoning symptoms. He did not agree that Lee died from croupous pneumonia; the primary cause of the man's death was arsenical poisoning. The condition of the lungs was secondary to the condition of the heart. The coroner pointed out that everyone agreed that Lee did suffer from arsenical poisoning. As to where he got his arsenic from that was rather a matter for the sanitary authorities than for them. The jury returned a unanimous verdict of "Death from pneumonia accelerated by arsenical poisoning." The coroner said, after the verdict had been given, that a gentleman had called on him and had told him how to conduct the inquiry. He, the coroner, would not mention his name, but he was connected with the brewery interest. As far as we can judge from the evidence given there would seem to be no doubt about the arsenic having a large share in the death of Lee. But a man who had old pleuritic adhesions, morbus cordis, bronchitis or pneumonia, or both, and who was in addition a confirmed drinker, carried about with him a "body of death" quite enough to kill him in a variety of ways. There need not be so much arsenic taken to set up severe symptoms, if it be taken in an organic form, or when associated with other things, or after it has been exposed to some process of fermentation. Arsenic, as is well known, was a favourite poison in mediæval times, and it was said to be far more efficacious if prepared by first administering it in a fatal dose to a pig or some animal. The body was then allowed to putrefy and the arsenical fluids distilled or otherwise extracted from the putrid mass were found to be of great potency. We are repeating the teachings of mediæval practice without guaranteeing their accuracy. But, possibly, the fermented compounds of arsenic nowadays may be far more virulent than any simple salt of the metal. It is difficult to see how arsenic could get into rum or whisky, two of Lee's favourite beverages, but in ale there are two possible sources—namely, invert sugar and malt. If brewing sugars are, since the Manchester epidemic of arsenical poisoning, generally pure we suppose the guilty substance must be the malt. We have taken our notes of the inquest from the *Halifax Courier* of Feb. 8th, which gives a full report, and is to be congratulated upon having done so.

## THE ARMY MEDICAL SERVICE.

ANY day now may see the appearance of the new Royal Warrant for the Royal Army Medical Corps; meanwhile a good deal of natural curiosity exists to know whether the warrant will fulfil all the reasonable expectations that have been raised in regard to it. Apart from all the questions that have arisen and have been keenly discussed in connexion with the report of Mr. Brodrick's Committee there are several matters calling for settlement on the part of the authorities. Professor T. Clifford Allbutt has very pointedly called attention to the unscientific, or even anti-scientific, tone of the service as one of its evils and as exercising a deterrent effect on medical candidates of a superior class: and he illustrates this by quoting the experience of a medical officer as to the deficiencies that exist in the supply of scientific, medical, and surgical appliances, and the lack of any sympathetic and appreciative spirit on the part of many of the senior medical officers of the service in encouraging their juniors to prosecute scientific researches and to keep abreast with the results of professional progress. How far these allegations are well founded at the present time we have not the means of knowing. The system of promotion by selection for the higher ranks, if honestly and properly carried this special type under the designation of 'feeble minded' I am still firmly convinced that this term should not be used in this restricted sense, but generally, and should embrace all classes and types of congenitally mentally deficient persons and that our imbecile institutions should as is done in America call themselves 'schools for the feeble minded', by this means many parents who from one reason or other refuse to have their children branded as idiots would no longer hesitate to take the advantages which our institutions so ably afford During the year 65 patients were discharged as relieved "It is very gratifying to be able to report that some of these were much benefited by their period of residence three being to a large extent self supporting and one earning 25*s* per week' The deaths during the year amounted to 15—viz, 11 males and four females, or 2 8 per cent of the average number resident Of the deaths four each were due to epilepsy and phthisis two to valvular disease of the heart, two to spinal caries and one each to 'scrofula tuberculosis, and diarrhœa' There had been no infectious disease with the exception of a few cases of chicken pox Important alterations and improvements have been made in the heating, lighting, ventilation, and sanitation of the building The board of management states in its report that the work in progress for the above alterations and improvements will involve an expenditure of nearly £15 000 Among the donations received is a sum of £1000 from an anonymous donor Various legacies have also been received during the year A conference was held by the invitation of the Duchess of Sutherland, at Stafford House on June 27th 1901 of the chairmen superintendents and secretaries of the four following voluntary asylums for idiots and imbeciles the institutions represented being Earlswood Asylum and the idiot asylums of Lancaster Colchester, and Starcross (Exeter) The object of the conference was "to consider how far cooperation between institutions for imbeciles and the National Association for Promoting the Welfare of the Feeble minded is practicable and desirable.' Unfortunately the conference ended without any practical results as to the object desired

*Roxburgh Berwick and Selkirk District Asylum, Melrose* (*Report for the year ending May 15th 1901*) —The average number of patients resident during the year was 307 comprising 142 males and 165 females The admissions during the year amounted to 58—viz, 30 males and 28 females Of these 42 were first admissions Dr J Carlyle Johnstone, the medical superintendent states in his report that the ordinary rate of board charged for private patients is £40 a year but that patients in straitened circumstances are received at lower rates when the board of management is furnished with satisfactory proof that the full rate cannot be paid Owing to want of accommodation however admission continues to be refused to all private patients except such as cannot possibly be provided for in other asylums or elsewhere' Hereditary predisposition to mental disorder was ascertained to exist in 34 of the patients admitted, or 58 per cent In 28 cases (48 per cent) suicidal tendencies were present and of these patients six had made serious attempts to terminate their lives before entering the asylum The physical condition of the patients admitted was good or average in nine cases bad in 45 cases and very bad in four cases In about 50 per cent of the admissions the patients suffered from some form or other of serious bodily disease "As usual there was a large proportion of aged congenital and chronic or relapsed cases, and in only a small percentage could ultimate recovery be expected while from the nature of their bodily and mental infirmities many of the cases were such as to require skilled nursing and hospital treatment The number of patients discharged as recovered during the year amounted to 15—viz, nine males and six females—or 4 8 per cent of the average number resident. The deaths during the year amounted to 16—viz 10 males and six females—or 5 per cent, as calculated on the same basis Of the deaths one was due to aneurysm of the aorta, two to senile decay four to pulmonary tuberculosis, five to general paralysis and the rest to other causes In 12 out of the 16 cases the cause of death was verified by post mortem examination The general health of the institution was good and there was no epidemic disorder 'The overcrowding of the male side continues says Dr Johnstone 'to increase. The arrangements afforded by the old wards for the treatment of recent and curable cases, the nursing of the sick, and the safeguarding of dangerous and anxious cases, are quite inadequate and unsuitable The male patients do not, in fact, receive that quality of care and treatment which can only be provided for them in an institution thoroughly equipped in accordance with those principles of science and humanity which govern the modern treatment of the insane Plans and specifications for the erection of a hospital block for male patients of a similar description to the female hospital (which serves its purpose admirably) are now receiving the consideration of the board The Commissioner in Lunacy states in his report that the general condition of the patients was highly satisfactory that the medical case books and records of necropsies were well kept, and that evidences of able and careful administration were everywhere apparent

*Northumberland County Asylum* (*Report for the year ending March 31st 1901*) —The average number of patients resident during the year was 634 and comprised 357 males and 277 females The admissions during the year amounted to 181—viz 90 males and 91 females Of these 151 were first admissions Dr T W McDowall, the medical superintendent states in his report that the admission rate remains high and that many unfavourable cases continue to be received The average number resident was the highest since the opening of the asylum This continued increase of male patients causes much overcrowding" For some years the work of the medical staff has been growing unduly heavy, and at the beginning of the year it was decided to appoint a female assistant medical officer for the female wards and the appointment was made shortly afterwards The number of patients discharged as recovered during the year amounted to 75—viz, 39 males and 36 females—or 11 8 per cent of the average number resident The deaths during the year amounted to 68 or 10 7 per cent., as calculated on the same basis Of the deaths four were due to senile decay, five to melancholia six to cardiac disease, 13 to general paralysis of the insane 15 to phthisis and other forms of tuberculosis and the rest to other causes The Commissioners in Lunacy state in their report that the wards were clean and well furnished the beds and dormitories in proper condition, the patients quiet and orderly and neatly clothed and the medical records fully and intelligently kept The committee of management state in its report that plans and estimates have been prepared for the erection of an isolation hospital. The rate of maintenance of pauper patients remains unchanged at 10*s* 6*d* per head per week

# ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on Feb 4th Dr T R Fraser, the President being in the chair —Dr D J Graham was introduced and took his seat as a Fellow of the College —Dr F J Tresilian and Dr J R Gilmour were admitted by ballot to the Fellowship of the College —On a ballot three candidates were admitted to the Membership of the College after examination —The Registrar reported that since the last quarterly meeting 33 persons had obtained the Licence of the College by examination —The Secretary reported that the Council had resolved to offer the Parkin Prize for competition during the current year the subject to be in terms of the bequest, On the Curative Effects of Carbonic Acid Gas or other Forms of Carbon in Cholera for Different Forms of Fever and Other Diseases Essays will be received by the Secretary up to Dec. 31st, 1902.—Intimation was made that the Council had determined to defer the award of the Freeland Barbour Fellowship from February to May biennially —The President announced that the Council had nominated the President and Vice President for the time being to be delegates to the Fourteenth International Medical Congress at Madrid —The Secretary read a statement which had been prepared by the Council and transmitted to the Secretary for War and the Secretary for Scotland protesting against the proposed representation of Scotland on the Advisory Board of the Royal Army Medical Corps as not calculated to give the medical profession of Scotland from whose medical schools a large percentage of successful candidates for the Royal Army Medical Corps is annually supplied, the confidence that is desirable in the work of the Board The conviction was expressed that the proposed appointment would lead to widespread dissatisfaction

# THE SANITARY INSTITUTE.

## DISCUSSION ON THE PREVENTION OF SMALL-POX IN LONDON.

AT a sessional meeting of the Sanitary Institute held in the Parkes Museum on Feb. 12th, under the chairmanship of Sir JAMES CRICHTON-BROWNE, Mr. A. WYNTER BLYTH opened a discussion on the Prevention of Small-pox in the Metropolis.

Mr. WYNTER BLYTH (medical officer of health of St. Marylebone) said that the various plagues which fell on man and beast occurred with a certain periodicity—that is to say, there were seasons of activity alternating with seasons of quiescence. In the latter periods inflammable material accumulated awaiting only a spark to flare up and be in part consumed. With regard to immunity from small-pox one attack of that disease usually immunised throughout life, but he had seen a man, aged 65 years, who was badly pitted from small-pox contracted when he was 20 years of age die from the confluent form of that malady. Vaccination inoculated a something so much akin to small-pox that it conferred the same kind of immunity but since a man might have small-pox twice it was foolish to expect a life-long immunity from a vaccination in childhood, for no one contended that vaccination protected longer or more efficiently than small-pox itself. Crude statistics threw unmerited discredit on revaccination. In the Sheffield epidemic there were 830 soldiers all of whom had been revaccinated some time or other. 12 of those men caught small-pox, but it was elicited that the revaccination in no one of the 12 had taken. Such a fact, to his mind, only showed that the operation ought to have been repeated and that it had not been properly performed. If one of the great scientific "magi" were to discover some wonderful fluid which would protect children from scarlet fever it would probably render scarlet fever no longer mainly a disease of children and the age-period most prone to the infection would be that from 15 to 25 years. The malady itself would also become rare from the lessened amount of infection. What he had pictured as possible with regard to scarlet fever had actually happened with regard to small-pox. The wonderful fluid that prevented small-pox had been discovered, but its influence as age advanced got weaker and weaker. He quoted statistics to show that as vaccination increased the incidence of the disease decreased in childhood but increased in adolescence. From preliminary statistics recently published by the Asylums Board he drew the conclusion that owing to the protection of vaccine lasting from five to 15 years the main incidence of small-pox was on adults, the least incidence being on children. This incidence, the effect of primary vaccination protecting children, was manifested in various local epidemics during past years. He contrasted the immunity of the revaccinated nurses in the small-pox hospitals with the rapidity with which small-pox spread in a partially protected community when the slightest chance contact bore fruit and from one single case 10 or even 20 others might have been directly derived. Discussing the influence of sanitary conditions on small-pox Mr. Blyth contended that no connexion had been established between insanitary conditions and the spread of small-pox in any epidemic. The one single condition that predominated over all sanitary conditions was the immunity acquired either from a previous attack of small-pox or from efficient vaccination. One of the most marked illustrations of this great truth was furnished by an incident which occurred in the Leicester epidemic The small-pox hospital staff there consisted of 40 persons. Of these 34 were more or less immune either from a previous revaccination or a previous attack of small-pox. One of these protected persons, whose revaccination was 10 years old, suffered from a mild attack of small-pox. Of the remaining six nurses who refused revaccination five out of the six contracted small-pox and one died from the disease The whole 40 persons were exposed to precisely the same sanitary conditions, and yet the malady selected the only group which medical opinion would have selected as insufficiently protected. Concerning the question whether the season of the year afforded grounds for what may be called a natural subsidence of the epidemic Mr. Blyth declared that so far as seasonal distribution could be judged the malady was likely, unless the efforts of the local authorities were aided by the public, to increase up to May and not decline until the first or second week in June. It was perfectly possible to arrest the epidemic in a single week. Beyond all disinfecting sprinklings, all cleansing of sewers, drains, and even persons, even beyond all hospital isolation, revaccination and vaccination formed the only potent preventive. In the romance of Samuel Butler entitled "Erewhon," a land was fabled in which illness of any kind was treated as criminal. However far-fetched such a notion with regard to maladies not arising from personal filth, immorality, or dissipation was, it was not so with regard to diseases which could be avoided by individual effort and which were dangerous to the public and seriously interfered with trade; such neglect was in its nature criminal and the time might come when it would be consistently treated as such. After isolation in hospital of a patient suffering from small-pox and after the usual disinfection and cleansing the question remained as to what should be done with those persons who had been in contact with the infectious sick and especially in regard to a class of persons homeless, generally very poor, and not a few amongst them indescribably filthy. The London County Council bribed such waifs to submit to virtual imprisonment to undergo quarantine. That at present was voluntary, but legislative enactment dealing with the matter was urgently needed.

Sir JAMES CRICHTON-BROWNE said that the perfect unanimity of opinion on the part of the medical profession in connexion with the prevention of small-pox was very striking and ought in itself powerfully to impress public opinion.

Dr. J. F. J. SYKES (medical officer of health of St. Pancras) detailed the beneficial effects following the appointment of medical referees for diagnosis in doubtful cases of small-pox.

Dr. J. G. GLOVER said that he wished to ventilate the question as to the inadequacy of the existing machinery for public vaccination. He called to their remembrance that it had been shown that the lymph supplied by the Government had no absolute monopoly of security. Some two years ago an investigation into the quality of the lymph supplied by Government and by private firms was made by THE LANCET, and it came out most distinctly that there were seven or eight lymphs as pure as the Government lymph. They knew that in Great Britain it did not do to trust everything to the Government. He agreed, however, that there should be some public standard to secure the purity of lymph. Dr. Glover also pointed out that the fact of rich people sending to the public vaccinator to be vaccinated prevented that officer from spending his time in vaccinating the poor. He recalled the fact that Glasgow had stopped its epidemic of small-pox by house-to-house visitation for the purpose of vaccination.

Dr. P. C. SMITH (medical officer of health of Wandsworth) recommended compulsory vaccination for every "contact" they came across.

Mr. SHIRLEY F. MURPHY (medical officer of health of the Administrative County of London), Dr. W. A. BOND (medical officer of health of Holborn), Mr. H. W. G. MACLEOD, and Mr. W. G. KERSHAW also addressed the meeting, which terminated with a hearty vote of thanks to the Chairman.

# ASYLUM REPORTS.

*Earlswood Asylum, Redhill, Surrey (Annual Report for 1900).*—The asylum admits idiots and imbeciles of higher mental grade. The average number of patients resident during the year was 529 and comprised 346 males and 183 females. The number of patients admitted during the year was 47—viz., 32 males and 15 females. Of the admissions six males and five females were over the age of 20 years, while the average age for males was 11·2 years and for females 16·14 years. A considerable proportion of the admissions, amounting to 23·4 per cent., consisted of epileptics—"a high rate for a class of case for which no prospect of permanent improvement can be offered." Dr. Charles Caldecott, the medical superintendent, states in his report that with the exception of epileptics the admissions are of a hopeful type for education and training. High-grade imbecile patients benefit to a great extent by the teaching and training received at the institution. "I regret," says Dr. Caldecott, "that persistent efforts should still be made to legislate for seeds, is admittedly a mixture of alkaloids, the most important of which are the crystalline veratrine and the amorphous veratridine, though several others have been reported—viz., sabadilline, sabatrine, sabadine, and sabadinine. It is important that so potent a drug as veratrine should be prepared in as pure and definite a state as possible; hence it is desirable that a process should be devised for preparing an alkaloid of definite composition. Damiana is reported to contain a bitter substance, resins and volatile oil. As the liquid extract of the leaves is now being extensively used a systematic examination of this drug is wanted. The same is required in the case of *Cereus grandiflorus*, *Citrullus colocynthis*, and *Cassia fistula*; in the case of colocynth the bitter glucoside, colocynthin, residing in the pulp but not in the seeds, is little understood, whilst it is not known to what the laxative properties of cassia pulp are due. The petals of the red poppy (*Papaver rhœas*) come in the same category; they contain a red colouring matter which is said to be due to two acids—viz, rhœdic and papaveric acids. Lastly, senna fruits have come into use in place of the leaves; it is desirable to know whether or not the constituents of the fruits and of the leaves are identical in composition and in amount

### *Chemical Problems.*

There are many problems, in this as well as in the other sections, which belong to the domain of the pharmacist alone—e.g., the improvement of the official process for the preparation of hydrargyri oleas. The subject of standardisation, however, is of direct importance to the medical profession. It is significant that the galenical preparations of most of the potent drugs in the Pharmacopœia still remain unstandardised; thus, aconite, stramonium, strophanthus, calabar bean, and colchicum may be cited. Ergot is another drug of immense importance for which there is no official process of standardisation. The well-known fact that ergot and its preparations do not maintain their potency indefinitely renders it very desirable that the next Pharmacopœia should remedy this deficiency. If it be found in this and in other drugs that chemical processes of assay are unsuitable or untrustworthy, then it is a question worthy of serious consideration whether steps should not be taken to establish trustworthy physiological standards of strength. It is noteworthy that a preparation of *Cannabis indica* which can be depended upon to contain the active principle of the drug is still a desideratum. Another point to be settled is the relative values of the two official senna leaves, the Indian and the Alexandrian. The Pharmacopœia permits them to be used indifferently.

### *Materia Medica.*

Two questions only will be referred to. In the official decoctum aloes compositum the use of saffron has long been a debatable question. As saffron is a costly drug the suggestion has been made that a less expensive flavouring agent should be substituted. It has yet to be proved, however, whether or not saffron is used merely as a flavouring agent. In ancient times it was used externally as well as internally as a medicine; it would scarcely enter into external applications for the sake of its colour and certainly not for its taste. According to Hanbury and Flückiger[3] saffron is of no use as a medicine and it retains a place in the Pharmacopœia solely on the ground of its utility as a colouring agent. Until this drug has been pharmacologically tested and found useless there is no evidence to warrant its exclusion from the Pharmacopœia except the fact that no definite principle obtained from it has been proved to have any particular pharmacological value. Several definite constituents have, however, been obtained from saffron, notably the glucoside crocin, an amorphous red colouring matter; picrocrocin, a colourless bitter principle; and volatile oil. The stimulant, antispasmodic, and emmenagogue properties ascribed to saffron, while lacking proof, are an argument in favour of its retention until the drug shall be proved to be useless. According to Sir Lauder Brunton[4] saffron has but little action. In this connexion it is of literary interest to mention that even from the earliest times saffron has been a costly drug. Thus, both Dioscorides and Pliny refer to the frauds practised on it, the latter remarking: "Adulteratur nihil æque." Lastly, the Research List of the British Pharmaceutical Conference suggests researches into the effects of cultivation, soil, climate, and time of collection on medicinal plants. Pharmaceutical chemists and others have been, and still are, steadily working out problems of this nature, but except in a few instances inquiries into the chemical and physiological characters of the principles of plants have not gone hand in hand. It is very desirable that in the future medical practitioners and pharmaceutical or other chemists should join hands in similar investigations, as has been done notably in the case of aconite by Professor Cash and Professor Wyndham R. Dunstan.

# Looking Back.

FROM

## THE LANCET, *SUNDAY, FEB.* 15, 1824.

### ST. THOMAS'S HOSPITAL.

FEB. 13.

*Case of Ague, cured by the Sulphate of Quinine.*

JOHN L. of Peterborough, æt. 32, was admitted into George's ward of this hospital Feb. 5th, with ague; says that for a fortnight previous to his admission he had been seized with a fit of shivering every second day, about eleven o'clock in the morning, which continued on him for about four hours. The patient was immediately ordered by Dr. ELLIOTSON, under whose care he is, three grains of sulphate of quinine every six hours, dissolved in water, with a minim of diluted sulphuric acid. Since he has taken this medicine, the shivering fit has not returned. Last year this same man had an attack of ague, which continued on him for four months.

*Case of sphacelus of the left foot.*

*Continued from page 158.*

The granulations at the lower part of the left leg appear quite healthy The right leg and foot have been swollen lately, but they have resumed their natural size. The same applications are continued.

*Operations.*—Feb. 13. A child three years old, underwent the operation of lithotomy. Two calculi were removed; the instrument used in dividing the prostate gland was Mr. BLIZARD's knife. The operator was Mr. TYRRELL.

A small cancer scroti, known by the name of the chimney-sweeper's cancer, was this day removed from one of those unfortunate individuals who are subjected to this disease by the nature of their occupation.—The complaint was quite in the incipient stage, the patient having first perceived it towards the latter end of last December. The part affected was not larger over than a sixpence, and it had on its surface a thin scab or incrustation of matter, with hard and slightly elevated edges—it was completely excised—one vessel secured—and a suture applied to the wound, to bring the edges together, and, lastly, strips of adhesive plaster were applied. The part removed was shewn to those present; when cut into, it had a whitish appearance.

A small carcinomatous tumour was also removed from just below the under lid of the left eye, and a little to the outer side.

Both operations were performed by Mr. GREEN.

The only accident worth noticing, is a fracture of the skull, from a kick of a horse, the history of which case we will give at some future time.

The nuisances we complained of last week, viz. the vending of porter, fruit, &c. in the wards of the Borough hospitals have not been stopt, therefore we shall take an early opportunity of showing the evil consequences tha' that is from them, and the degree of culpability attriction was ex- different officers for allowing them to exist, ould lead to wide-as he is within the hospital, a suit of brown holland overalls, consisting of coat, trousers, and cap, which will be provided by the Board; (6) any legally qualified medical man may attend the hospital for purposes of instruction as if he were a student; (7) in order that qualified medical men who have not sufficient leisure to attend a prolonged course of instruction may have opportunities of seeing cases of small-pox demonstrations will be given from time to time, the fees charged being one guinea per demonstration or two guineas for three demonstrations; and (8) the rules as to disinfection and vaccination shall apply equally to medical men and students. The Board will, no doubt, give public intimation of the time when the foregoing scheme may become operative. At the same meeting of the Board a letter was read from Dr. T. O. Dudfield, medical officer of health of the borough of Kensington, suggesting that experts appointed by the Board should assist practitioners in the diagnosis of doubtful cases of small-pox before the removal of the patients from their homes. This might be useful in some degree; but, on the other hand, during an epidemic a considerable staff of experts might be required and delay in the removal of genuine cases of small-pox might be occasioned. The suggestion was therefore not adopted. As is generally known, all cases of presumed small-pox are examined by a medical officer at the Board's wharves before the journey in the steamer down the river to the hospital.

## THE SOCIETY OF PUBLIC ANALYSTS.

THE twenty-seventh annual dinner of the Society of Public Analysts was held on Wednesday evening last, Feb. 12th, at the Hotel Cecil. Dr. J. Augustus Voelcker, President of the Society, was in the chair, and was well supported by the leading members of the Society. The guests included Mr. T. H. Elliott, C.B., the Secretary to the Board of Agriculture; Sir Ernest Clarke, Secretary to the Royal Agricultural Society; Professor T. E. Thorpe, C.B., director of the Government Laboratories; Professor H. E. Armstrong, Professor of Chemistry at the City and Guilds of London Central Institute; and Mr. W. R. Bousfield, K.C., M.P. Eloquent testimony to the sound value of the work done by the Society of Public Analysts was forthcoming in the speeches of Mr. Elliott and Professor Thorpe replying to the toast of "The Public Departments," and in that of Professor W. A. Tilden, who submitted the toast of the evening: "The Work of the Society." Dr. Voelcker, replying to Professor Tilden, gave an excellent exposition of the work and aims of the Society of Public Analysts, interspersed with humorous anecdotes as to the public conception in days not long gone by of what was implied by the title of "chemist." Sir Ernest Clarke was witty and Professor Armstrong was commendably brief in replying to the toast of "The Guests." Altogether the gathering was a thoroughly pleasant and successful one and fulfilled the object of such annual dinners very completely, for on all sides testimony to the value of the work of the society was elicited.

## UNIVERSITY OF LONDON FACULTY OF MEDICINE.

A MEETING of the faculty of medicine of the University of London will be held at the University buildings at 5 P.M. on Feb. 21st. The business will be the further consideration of the question of the concentration of intermediate and preliminary medical studies. In view of the recent large accession of new members, who have not been able to take part in the former discussions on this subject, Mr. H. T. Butlin, the dean of the faculty, will make a short statement as to the work of the faculty in connexion with "concentration" during the past year.

THE anniversary dinner of the Medical Society of London will be held at the Whitehall Rooms of the Hôtel Métropole on Saturday, March 8th, at 7.30 P.M. Communications should be addressed to the honorary secretaries, Dr. Arthur F. Voelcker and Mr. Jonathan Hutchinson, jun., at 11, Chandos-street, W.

THE President of the Republic of Venezuela has conferred upon Dr. Oscar Jennings of Paris the Order of Commander of the Bolivar (Busto del Libertador).

# Pharmacological Notes.

### ON SOME UNSOLVED PROBLEMS AS TO THE CHEMISTRY OF DRUGS.

NOT the least important portion of the work of the British Pharmaceutical Conference consists in the encouragement of research. In a list published under the auspices of the conference hints are given as to various problems connected with the analysis of plants, chemistry, materia medica, and pharmacy that await investigation.

*Problems in the Analysis of Plants.*

There are quite a number of important drugs of which the active principles are as yet either unknown or imperfectly understood. Thus, the bark of cascara sagrada is known to contain certain resins, one of which is said to have a bitter taste, but their chemical nature is not known.[1] The rhizome of *Cimicifuga racemosa* has an acrid, bitter taste which has been attributed to a crystalline substance, racemonin, but it is not known to what constituent or constituents the activity of the rhizome is due. There are many other drugs of which our knowledge is incomplete and brief reference will be made to some of them. *Euphorbia pilulifera:* Investigations have so far failed to isolate any particular constituent. The chemical constitution of the acrid principle of mezereon bark, named "mezerein," is required; it has sternutatory properties and has been described as a greenish-brown amorphous resin. The flowers and root of *Arnica montana* have been found to contain a bitter principle, arnicin, consisting of minute yellow deliquescent crystals, but its constitution has not been decided, nor is it known whether the flowers contain, as has been stated, more arnicin than does the root. Of the bitter principle of chamomile flowers, termed "anthemic acid," little that is definite is known. The same applies to the purgative principle of the castor-oil seed; as the fixed oil possesses well-known mild purgative properties it is probable that at least some of this principle is extracted from the seeds with the oil. The latter consists of the glycerides of ricinoleic and ricin-isoleic acids, but whether these glycerides in their pure state or the fatty acids themselves are purgative or not is undecided. The cake that is left after the expression of the oil is more violent in its action than the whole seeds or the oil itself. From this cake a purgative substance, ricinone, has been isolated, as well as an extremely poisonous principle, ricin; the latter body belongs apparently to the class of albumoses; it produces inflammatory symptoms and is not purgative.[2] Little appears to be known definitely regarding the active principle of taraxacum root. It is desirable to know to what constituents its cholagogue and diuretic properties are due. A small quantity of a crystalline bitter substance, taraxacin, has been obtained from the root, also an acrid principle, neither of which, however, has been closely examined. The former constituent appears to be susceptible of decomposition, as the extract prepared from the fresh root is often almost devoid of bitterness. The medicinal virtues of the bladderwrack (*Fucus vesiculosus*) have been attributed solely to the presence of iodine and bromine. It is not improbable that this seaweed may also contain some organic constituent of importance. According to Eschle the iodine exists in the form of an organic compound similar in its nature to the iodine compound found in thyroid glands. A gelatin-like substance, algin, has also been obtained from this drug. It remains to be proved what is the most important constituent. Veratrine, as obtained from cevadilla this special type under the designation of 'feeble-minded.' I am still firmly convinced that this term should not be used n this restricted sense, but generally, and should embrace all classes and types of congenitally mentally deficient persons ...... and that our imbecile institutions should, as is done in America, call themselves 'schools for the feeble-minded'; by this means many parents who from one reason or other refuse to have their children branded as idiots would no longer hesitate to take the advantages which our institutions so ably afford." During the year 65 patients were discharged as relieved. "It is very gratifying to be able to report that some of these were much benefited by their period of residence, three being to a large extent self-supporting and one earning 25*s.* per week." The deaths during the year amounted to 15—viz., 11 males and four females, or 2·8 per cent. of the average number resident. Of the deaths, four each were due to epilepsy and phthisis, two to valvular disease of the heart, two to spinal caries, and one each to "scrofula, tuberculosis, and diarrhœa." There had been no infectious disease, with the exception of a few cases of chicken-pox. Important alterations and improvements have been made in the heating, lighting, ventilation, and sanitation of the building. The board of management states in its report that the work in progress for the above alterations and improvements will involve an expenditure of nearly £15,000. Among the donations received is a sum of £1000 from an anonymous donor. Various legacies have also been received during the year. A conference was held, by the invitation of the Duchess of Sutherland, at Stafford House on June 27th, 1901, of the chairmen, superintendents, and secretaries of the four following voluntary asylums for idiots and imbeciles, the institutions represented being Earlswood Asylum and the idiot asylums of Lancaster, Colchester, and Starcross (Exeter). The object of the conference was "to consider how far coöperation between institutions for imbeciles and the National Association for Promoting the Welfare of the Feeble-minded is practicable and desirable." Unfortunately, the conference ended without any practical results as to the object desired.

---

[1] Compare Greenish's Materia Medica, to which reference has been made in this and other cases cited.

[2] Ibid., p. 160.

*Roxburgh, Berwick, and Selkirk District Asylum, Melrose* (*Report for the year ending May 15th, 1901*).—The average number of patients resident during the year was 307, comprising 142 males and 165 females. The admissions during the year amounted to 58—viz., 30 males and 28 females. Of these 42 were first admissions. Dr. J. Carlyle Johnstone, the medical superintendent, states in his report that the ordinary rate of board charged for private patients is £40 a year, but that patients in straitened circumstances are received at lower rates when the board of management is furnished with satisfactory proof that the full rate cannot be paid. "Owing to want of accommodation, however, admission continues to be refused to all private patients except such as cannot possibly be provided for in other asylums or elsewhere." Hereditary predisposition to mental disorder was ascertained to exist in 34 of the patients admitted, or 58 per cent. In 28 cases (48 per cent.) suicidal tendencies were present and of these patients six had made serious attempts to terminate their lives before entering the asylum. The physical condition of the patients admitted was good or average in nine cases, bad in 45 cases, and very bad in four cases. In about 50 per cent. of the admissions the patients suffered from some form or other of serious bodily disease. "As usual, there was a large proportion of aged, congenital and chronic, or relapsed cases, and in only a small percentage could ultimate recovery be expected, while from the nature of their bodily and mental infirmities many of the cases were such as to require skilled nursing and hospital treatment." The number of patients discharged as recovered during the year amounted to 15—viz., nine males and six females—or 4 8 per cent. of the average number resident. The deaths during the year amounted to 16—viz., 10 males and six females—or 5· per cent., as calculated on the same basis. Of the deaths one was due to aneurysm of the aorta, two to senile decay, four to pulmonary tuberculosis, five to general paralysis, and the rest to other causes. In 12 out of the 16 cases the cause of death was verified by post-mortem examination. The general health of the institution was good and there was no epidemic disorder. "The overcrowding of the male side continues," says Dr. Johnstone, "to increase. The arrangements afforded by the old wards for the treatment of recent and curable cases, the nursing of the sick, and the safeguarding of dangerous and anxious cases, are quite inadequate and unsuitable. The male patients do not, in fact, receive that quality of care and treatment ...... which can only be provided for them in an institution thoroughly equipped in accordance with those principles of science and humanity which govern the modern treatment of the insane. ...... Plans and specifications for the erection of a hospital block for male patients, of a similar description to the female hospital (which serves its purpose admirably), are now receiving the consideration of the board." The Commissioner in Lunacy states in his report that the general condition of the patients was highly satisfactory, that the medical case-books and records of necropsies were well kept, and that evidences of able and careful administration were everywhere apparent.

*Northumberland County Asylum* (*Report for the year ending March 31st, 1901*).—The average number of patients resident during the year was 634 and comprised 357 males and 277 females. The admissions during the year amounted to 181—viz., 90 males and 91 females. Of these 151 were first admissions. Dr. T. W. McDowall, the medical superintendent, states in his report that the admission-rate remains high and that many unfavourable cases continue to be received. "The average number resident was the highest since the opening of the asylum. This continued increase of male patients causes much overcrowding." For some years the work of the medical staff has been growing unduly heavy, and at the beginning of the year it was decided to appoint a female assistant medical officer for the female wards, and the appointment was made shortly afterwards. The number of patients discharged as recovered during the year amounted to 75—viz., 39 males and 36 females—or 11·8 per cent. of the average number resident. The deaths during the year amounted to 68, or 10·7 per cent., as calculated on the same basis. Of the deaths four were due to senile decay, five to melancholia, six to cardiac disease, 13 to general paralysis of the insane, 15 to phthisis and other forms of tuberculosis, and the rest to other causes. The Commissioners in Lunacy state in their report that the wards were clean and well furnished, the beds and dormitories in proper condition, the patients quiet and orderly and neatly clothed, and the medical records fully and intelligently kept. The committee of management state in its report that plans and estimates have been prepared for the erection of an isolation hospital. The rate of maintenance of pauper patients remains unchanged at 10*s.* 6*d.* per head per week.

## ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on Feb. 4th, Dr. T. R. Fraser, the President, being in the chair.—Dr. D. J. Graham was introduced and took his seat as a Fellow of the College.—Dr. F. J. Tresilian and Dr. J. R. Gilmour were admitted by ballot to the Fellowship of the College.—On a ballot three candidates were admitted to the Membership of the College, after examination.—The Registrar reported that since the last quarterly meeting 33 persons had obtained the Licence of the College by examination.—The Secretary reported that the Council had resolved to offer the Parkin Prize for competition during the current year, the subject to be, in terms of the bequest, "On the Curative Effects of Carbonic Acid Gas or other Forms of Carbon in Cholera, for Different Forms of Fever and Other Diseases." Essays will be received by the Secretary up to Dec. 31st, 1902.—Intimation was made that the Council had determined to defer the award of the Freeland Barbour Fellowship from February to May biennially.—The President announced that the Council had nominated the President and Vice-President for the time being to be delegates to the Fourteenth International Medical Congress at Madrid.—The Secretary read a statement which had been prepared by the Council and transmitted to the Secretary for War and the Secretary for Scotland, protesting against the proposed representation of Scotland on the Advisory Board of the Royal Army Medical Corps as not calculated to give the medical profession of Scotland, from whose medical schools a large percentage of successful candidates for the Royal Army Medical Corps is annually supplied, the confidence that is desirable in the work of the Board. The conviction was expressed that the proposed appointment would lead to widespread dissatisfaction.

# THE SANITARY INSTITUTE.

## DISCUSSION ON THE PREVENTION OF SMALL-POX IN LONDON.

AT a sessional meeting of the Sanitary Institute held in the Parkes Museum on Feb. 12th, under the chairmanship of Sir JAMES CRICHTON-BROWNE, Mr. A. WYNTER BLYTH opened a discussion on the Prevention of Small-pox in the Metropolis.

Mr. WYNTER BLYTH (medical officer of health of St. Marylebone) said that the various plagues which fell on man and beast occurred with a certain periodicity—that is to say, there were seasons of activity alternating with seasons of quiescence. In the latter periods inflammable material accumulated awaiting only a spark to flare up and be in part consumed. With regard to immunity from small-pox one attack of that disease usually immunised throughout life, but he had seen a man, aged 65 years, who was badly pitted from small-pox contracted when he was 20 years of age die from the confluent form of that malady. Vaccination inoculated a something so much akin to small-pox that it conferred the same kind of immunity but since a man might have small-pox twice it was foolish to expect a life-long immunity from a vaccination in childhood, for no one contended that vaccination protected longer or more efficiently than small-pox itself. Crude statistics threw unmerited discredit on revaccination. In the Sheffield epidemic there were 830 soldiers all of whom had been revaccinated some time or other. 12 of those men caught small-pox, but it was elicited that the revaccination in no one of the 12 had taken. Such a fact, to his mind, only showed that the operation ought to have been repeated and that it had not been properly performed. If one of the great scientific "magi" were to discover some wonderful fluid which would protect children from scarlet fever it would probably render scarlet fever no longer mainly a disease of children and the age-period most prone to the infection would be that from 15 to 25 years. The malady itself would also become rare from the lessened amount of infection. What he had pictured as possible with regard to scarlet fever had actually happened with regard to small-pox. The wonderful fluid that prevented small-pox had been discovered, but its influence as age advanced got weaker and weaker. He quoted statistics to show that as vaccination increased the incidence of the disease decreased in childhood but increased in adolescence. From preliminary statistics recently published by the Asylums Board he drew the conclusion that owing to the protection of vaccine lasting from five to 15 years the main incidence of small-pox was on adults, the least incidence being on children. This incidence, the effect of primary vaccination protecting children, was manifested in various local epidemics during past years. He contrasted the immunity of the revaccinated nurses in the small-pox hospitals with the rapidity with which small-pox spread in a partially protected community when the slightest chance contact bore fruit and from one single case 10 or even 20 others might have been directly derived. Discussing the influence of sanitary conditions on small-pox Mr. Blyth contended that no connexion had been established between insanitary conditions and the spread of small-pox in any epidemic. The one single condition that predominated over all sanitary ditions was the immunity acquired either from a previous of small-pox or from efficient vaccination. One of marked illustrations of this great truth was y an incident which occurred in the Leicester he small-pox hospital staff there consisted of ese 34 were more or less immune either from tion or a previous attack of small-pox. d persons, whose revaccination was n a mild attack of small-pox. Of ho refused revaccination five out pox and one died from the were exposed to precisely the he malady selected the only have selected as insuffi- uestion whether the what may be called Mr. Blyth declared ld be judged the orts of the local authorities to increase up to May and not decline until the first or second week in June. It was perfectly possible to arrest the epidemic in a single week. Beyond all disinfecting sprinklings, all cleansing of sewers, drains, and even persons, even beyond all hospital isolation, revaccination and vaccination formed the only potent preventive. In the romance of Samuel Butler entitled "Erewhon," a land was fabled in which illness of any kind was treated as criminal. However far-fetched such a notion with regard to maladies not arising from personal filth, immorality, or dissipation was, it was not so with regard to diseases which could be avoided by individual effort and which were dangerous to the public and seriously interfered with trade; such neglect was in its nature criminal and the time might come when it would be consistently treated as such. After isolation in hospital of a patient suffering from small-pox and after the usual disinfection and cleansing the question remained as to what should be done with those persons who had been in contact with the infectious sick and especially in regard to a class of persons homeless, generally very poor, and not a few amongst them indescribably filthy. The London County Council bribed such waifs to submit to virtual imprisonment to undergo quarantine. That at present was voluntary, but legislative enactment dealing with the matter was urgently needed.

Sir JAMES CRICHTON-BROWNE said that the perfect unanimity of opinion on the part of the medical profession in connexion with the prevention of small-pox was very striking and ought in itself powerfully to impress public opinion.

Dr. J. F. J. SYKES (medical officer of health of St. Pancras) detailed the beneficial effects following the appointment of medical referees for diagnosis in doubtful cases of small-pox.

Dr. J. G. GLOVER said that he wished to ventilate the question as to the inadequacy of the existing machinery for public vaccination. He called to their remembrance that it had been shown that the lymph supplied by the Government had no absolute monopoly of security. Some two years ago an investigation into the quality of the lymph supplied by Government and by private firms was made by THE LANCET, and it came out most distinctly that there were seven or eight lymphs as pure as the Government lymph. They knew that in Great Britain it did not do to trust everything to the Government. He agreed, however, that there should be some public standard to secure the purity of lymph. Dr. Glover also pointed out that the fact of rich people sending to the public vaccinator to be vaccinated prevented that officer from spending his time in vaccinating the poor. He recalled the fact that Glasgow had stopped its epidemic of small-pox by house-to-house visitation for the purpose of vaccination.

Dr. P. C. SMITH (medical officer of health of Wandsworth) recommended compulsory vaccination for every "contact" they came across.

Mr. SHIRLEY F. MURPHY (medical officer of health of the Administrative County of London), Dr. W. A. BOND (medical officer of health of Holborn), Mr. H. W. G. MACLEOD, and Mr. W. G. KERSHAW also addressed the meeting, which terminated with a hearty vote of thanks to the Chairman

# ASYLUM REPORTS.

*Earlswood Asylum, Redhill, Surrey (Annual Report for 1900).*—The asylum admits idiots and imbeciles of higher mental grade. The average number of patients resident during the year was 529 and comprised 346 males and 183 females. The number of patients admitted during the year was 47—viz., 32 males and 15 females. Of the admissions six males and five females were over the age of 20 years, while the average age for males was 11·2 years and for females 16·14 years. A considerable proportion of the admissions, amounting to 23·4 per cent., consisted of epileptics—"a high rate for a class of case for which no prospect of permanent improvement can be offered." Dr. Charles Caldecott, the medical superintendent, states in his report that with the exception of epileptics the admissions are of a hopeful type for education and training. High-grade imbecile patients benefit to a great extent by the teaching and training received at the institution. "I regret," says Dr. Caldecott, "that persistent efforts should still be made to legislate for

# VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 9045 births and 5875 deaths were registered during the week ending Feb. 8th. The annual rate of mortality in these towns, which had been 17·7, 17·7, and 17·9 per 1000 in the three preceding weeks, further rose to 20·6 per 1000 last week. In London the death-rate was 22·5 per 1000, while it averaged 19·8 in the 75 other large towns. The lowest death-rates in these towns were 8·8 in Coventry, 9·6 in West Hartlepool, 12·5 in Derby, 12·9 in Grimsby, 13·1 in Hornsey, and 13·5 in East Ham; the highest rates were 26·0 in Burnley, 26·1 in Rotherham, 26·3 in Rhondda, 26·8 in Sunderland, 28 0 in Wigan and Preston, and 28 8 in Merthyr Tydfil. The 5875 deaths in these towns last week included 583 which were referred to the principal zymotic diseases, against 534 and 512 in the two preceding weeks; of these 583 deaths 129 resulted from whooping-cough, 127 from measles, 102 from diphtheria, 77 from small-pox, 60 from scarlet fever, 49 from "fever" (principally enteric), and 39 from diarrhœa. No death from any of these diseases was recorded in Hastings, Burton-on-Trent, Handsworth, Smethwick, Grimsby, Derby, Wallasey, Tynemouth, or Newport (Mon.); in the other towns the highest zymotic mortality occurred in East Ham, Bournemouth, Aston Manor, Rotherham, Stockton-on-Tees, and Rhondda. The greatest proportional mortality from measles was recorded in Rotherham, Stockton-on-Tees, and Merthyr Tydfil; from "fever" in South Shields and Gateshead; from diphtheria in Willesden, Portsmouth, Bournemouth, Hanley, and Cardiff; from whooping-cough in East Ham, Plymouth, Aston Manor, Liverpool, Stockton-on-Tees, and Rhondda; and from "fever" in Walsall and West Hartlepool. 64 deaths from small-pox of persons belonging to London were registered last week, seven of persons belonging to West Ham, three to Tottenham, and one each to Walthamstôw, Reading, and Swansea, but not one to any other of the 76 large towns. There were 1102 small-pox patients under treatment in the Metropolitan Asylums hospitals on Saturday, Feb. 8th, against 877, 870, and 1135 at the end of the three preceding weeks; 287 new cases were admitted during the week, against 213, 204, and 499 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2500, against numbers decreasing from 3137 to 2554 on the six preceding Saturdays; 227 new cases were admitted during the week, against 288, 299, and 226 in the three preceding weeks. The deaths in London referred to diseases of the respiratory organs, which had been 307, 357, and 375 in the three preceding weeks, further rose last week to 486, and were 32 above the corrected average. Influenza was certified as the primary cause of 40 deaths in London last week, against 23, 18, and 26 in the three preceding weeks. The causes of 81, or 1·4 per cent., of the deaths in the 76 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bolton, Salford, Newcastle, Cardiff, and 32 other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, St. Helens, Warrington, Preston, Sheffield, and South Shields.

## HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3 and 21·8 per 1000 in the two preceding weeks, further increased to 23·9 per 1000 during the week ending Feb. 8th, and exceeded by 3 3 per 1000 the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 20·5 in Leith and 23·1 in Dundee to 24·3 in Edinburgh and 26·5 in Greenock. The 771 deaths in these towns included 23 which were referred to diarrhœa, 19 to measles, 17 to whooping-cough, 10 to scarlet fever, eight to diphtheria, five to "fever," and one to small-pox. In all 83 deaths resulted from these principal zymotic diseases last week, against 76 and 66 in the two preceding weeks. These 83 deaths were equal to an annual rate of 2·6 per 1000, which was 0·6 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 20 and eight in the two preceding weeks, rose again last week to 23, of which nine occurred in Glasgow, five in Dundee, four in Edinburgh, and three in Aberdeen. The deaths from measles, which had been 31 and 23 in the two preceding weeks, further declined to 19 last week, and included 16 in Glasgow and two in Greenock. The fatal cases of whooping-cough, which had been 11, 13, and 19 in the three preceding weeks, declined again last week to 17, of which 10 were registered in Glasgow, four in Paisley, and two in Aberdeen. The deaths from scarlet fever, which had been four and seven in the two preceding weeks, further rose to 10 last week, and included five in Glasgow, two in Aberdeen, and two in Greenock. The fatal cases of diphtheria, which had been five in each of the two preceding weeks, increased last week to eight, of which four occurred in Glasgow and two in Aberdeen. The deaths referred to different forms of "fever," which had been four, three, and three in the three preceding weeks, rose again to five last week, and included two in Glasgow and two in Edinburgh. The fatal case of small-pox was registered in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 128 and 141 in the two preceding weeks, further rose last week to 173, and were 15 in excess of the number in the corresponding period of last year. The causes of 21, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

## HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·9 and 22·7 per 1000 in the two preceding weeks, further rose to 23·8 per 1000 during the week ending Feb. 8th. During the past four weeks the death-rate has averaged 22·7 per 1000, the rates during the same period being 19·8 in London and 19 9 in Edinburgh. The 173 deaths of persons belonging to Dublin registered during the week under notice were eight in excess of the number in the preceding week, and included five which were referred to the principal zymotic diseases, against six, eight, and four in the three preceding weeks; of these, two resulted from whooping-cough, two from "fever," and one from diarrhœa. These five deaths were equal to an annual rate of 0·7 per 1000, the zymotic death-rate last week being 2·4 in London and 1·1 in Edinburgh. The 173 deaths in Dublin last week included 28 of children under one year of age and 45 of persons aged upwards of 60 years; the deaths of infants considerably exceeded the number recorded in the preceding week, while those of elderly persons showed a decline. Three inquest cases and five deaths from violence were registered; and 53, or nearly one-third, of the deaths occurred in public institutions. The causes of 14, or more than 8 per cent., of the deaths in Dublin last week were not certified.

## VITAL STATISTICS OF LONDON DURING 1901.

Complete statistics relating to sickness and mortality during the year 1901 in each of the cities and boroughs in the county of London are summarised in the accompanying table. The mortality figures relate to the deaths of persons actually belonging to the various metropolitan boroughs, and are the result of a complete system of distribution of deaths occurring in the institutions of London among the various boroughs in which the patients had previously resided. With regard to the notified cases of infectious diseases in London during 1901, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 8·9 per 1000 of the population, estimated at 4,543,757 persons in the middle of last year. In the three preceding years the rates had been 8·3, 9·3, and 7·7 per 1000 respectively. Among the various metropolitan boroughs the lowest rates were 5 3 in Chelsea, 5·8 in the City of Westminster, 5 9 in Kensington and in Hampstead, and 6·0 in Woolwich; the highest rates were 11 3 in St. Pancras and in Southwark, 11·4 in Hackney, 12·9 in Bethnal Green and in Bermondsey, and 13·1 in Holborn. The prevalence of small-pox in London during 1901 greatly exceeded that in any recent year; the number of new cases notified during the year was 1702, against 32, 29, and 88 in the three preceding years. This disease was proportionally most prevalent in the City of Westminster, St. Marylebone, St. Pancras, Holborn, Finsbury, and Bermondsey. The number of small-pox patients admitted into the Metropolitan Asylums hospitals during 1901 was 1788, and 666 remained under treatment at the end of the year. The prevalence

## HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 9345 births and 5875 deaths were registered during the week ending Feb. 8th. The annual rate of mortality in these towns, which had been 17·7, 17·7, and 17·9 per 1000 in the three preceding weeks, further rose to 20·6 per 1000 last week. In London the death-rate was 22·5 per 1000, while it averaged 19·8 in the 75 other large towns. The lowest death-rates in these towns were 8·8 in Coventry, 9·6 in West Hartlepool, 12·5 in Derby, 12·9 in Grimsby, 13·1 in Hornsey, and 13·5 in East Ham; the highest rates were 26·0 in Burnley, 26·1 in Rotherham, 26·3 in Rhondda, 26·8 in Sunderland, 28·0 in Wigan and Preston, and 28·8 in Merthyr Tydfil. The 5875 deaths in these towns last week included 583 which were referred to the principal zymotic diseases, against 534 and 512 in the two preceding weeks; of these 583 deaths 129 resulted from whooping-cough, 127 from measles, 102 from diphtheria, 77 from small-pox, 60 from scarlet fever, 49 from "fever" (principally enteric), and 39 from diarrhœa. No death from any of these diseases was recorded in Hastings, Burton-on-Trent, Handsworth, Smethwick, Grimsby, Derby, Wallasey, Tynemouth, or Newport (Mon.); in the other towns the highest zymotic mortality occurred in East Ham, Bournemouth, Aston Manor, Rotherham, Stockton-on-Tees, and Rhondda. The greatest proportional mortality from measles was recorded in Rotherham, Stockton-on-Tees, and Merthyr Tydfil; from "fever" in South Shields and Gateshead; from diphtheria in Willesden, Portsmouth, Bournemouth, Hanley, and Cardiff; from whooping-cough in East Ham, Plymouth, Aston Manor, Liverpool, Stockton-on-Tees, and Rhondda; and from "fever" in Walsall and West Hartlepool. 64 deaths from small-pox of persons belonging to London were registered last week, seven of persons belonging to West Ham, three to Tottenham, and one each to Walthamstow, Reading, and Swansea, but not one to any other of the 76 large towns. There were 1102 small-pox patients under treatment in the Metropolitan Asylums hospitals on Saturday, Feb. 8th, against 877, 870, and 1135 at the end of the three preceding weeks; 287 new cases were admitted during the week, against 213, 204, and 499 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2500, against numbers decreasing from 3137 to 2554 on the six preceding Saturdays; 227 new cases were admitted during the week, against 288, 299, and 226 in the three preceding weeks. The deaths in London referred to diseases of the respiratory organs, which had been 307, 357, and 375 in the three preceding weeks, further rose last week to 486, and were 32 above the corrected average. Influenza was certified as the primary cause of 40 deaths in London last week, against 23, 18, and 26 in the three preceding weeks. The causes of 81, or 1·4 per cent., of the deaths in the 76 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bolton, Salford, Newcastle, Cardiff, and 32 other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, St. Helens, Warrington, Preston, Sheffield, and South Shields.

## HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3 and 21·8 per 1000 in the two preceding weeks, further increased to 23·9 per 1000 during the week ending Feb. 8th, and exceeded by 3·3 per 1000 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 20·5 in Leith and 23·1 in Dundee to 24·3 in Edinburgh and 26·5 in Greenock. The 771 deaths in these towns included 23 which were referred to diarrhœa, 19 to measles, 17 to whooping-cough, 10 to scarlet fever, eight to diphtheria, five to "fever," and one to small-pox. In all 83 deaths resulted from these principal zymotic diseases last week, against 76 and 66 in the two preceding weeks. These 83 deat[illegible] [illegible] rate of 2·6 per 10[illegible]00, which [illegible] equal to the mean rate last we[illegible] from t[illegible] r 1000 [illegible] large English town[illegible] fatal [illegible] in which had been 20 and eight in the two preceding weeks, rose again last week to 23, of which nine occurred in Glasgow, five in Dundee, four in Edinburgh, and three in Aberdeen. The deaths from measles, which had been 31 and 23 in the two preceding weeks, further declined to 19 last week, and included 15 in Glasgow and two in Greenock. The fatal cases of whooping-cough, which had been 11, 13, and 19 in the three preceding weeks, declined again last week to 17, of which 10 were registered in Glasgow, four in Paisley, and two in Aberdeen. The deaths from scarlet fever, which had been four and seven in the two preceding weeks, further rose to 10 last week, and included five in Glasgow, two in Aberdeen, and two in Greenock. The fatal cases of diphtheria, which had been five in each of the two preceding weeks, increased last week to eight, of which four occurred in Glasgow and two in Aberdeen. The deaths referred to different forms of "fever," which had been four, three, and three in the three preceding weeks, rose again to five last week, and included two in Glasgow and two in Edinburgh. The fatal case of small-pox was registered in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 128 and 141 in the two preceding weeks, further rose last week to 173, and were 15 in excess of the number in the corresponding period of last year. The causes of 21, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

## HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·9 and 22·7 per 1000 in the two preceding weeks, further rose to 23·8 per 1000 during the week ending Feb. 8th. During the past four weeks the death-rate has averaged 22·7 per 1000, the rates during the same period being 19·8 in London and 19·9 in Edinburgh. The 173 deaths of persons belonging to Dublin registered during the week under notice were eight in excess of the number in the preceding week, and included five which were referred to the principal zymotic diseases, against six, eight, and four in the three preceding weeks; of these, two resulted from whooping-cough, two from "fever," and one from diarrhœa. These five deaths were equal to an annual rate of 0·7 per 1000, the zymotic death-rate last week being 2·4 in London and 1·1 in Edinburgh. The 173 deaths in Dublin last week included 28 of children under one year of age and 45 of persons aged upwards of 60 years; the deaths of infants considerably exceeded the number recorded in the preceding week, while those of elderly persons showed a decline. Three inquest cases and five deaths from violence were registered; and 53, or nearly one-third, of the deaths occurred in public institutions. The causes of 14, or more than 8 per cent., of the deaths in Dublin last week were not certified.

## HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 9045 births and 5875 deaths were registered during the week ending Feb. 8th. The annual rate of mortality in these towns, which had been 17·7, 17·7, and 17·9 per 1000 in the three preceding weeks, further rose to 20·6 per 1000 last week. In London the death-rate was 22·5 per 1000, while it averaged 19·8 in the 75 other large towns. The lowest death-rates in these towns were 8·8 in Coventry, 9·6 in West Hartlepool, 12·5 in Derby, 12·9 in Grimsby, 13·1 in Hornsey, and 13·5 in East Ham; the highest rates were 26·0 in Burnley, 26·1 in Rotherham, 26·3 in Rhondda, 26·8 in Sunderland, 28·0 in Wigan and Preston, and 28·8 in Merthyr Tydfil. The 5875 deaths in these towns last week included 583 which were referred to the principal zymotic diseases, against 534 and 512 in the two preceding weeks; of these 583 deaths 129 resulted from whooping-cough, 127 from measles, 102 from diphtheria, 77 from small-pox, 60 from scarlet fever, 49 from "fever" (principally enteric), and 39 from diarrhœa. No death from any of these diseases was recorded in Hastings, Burton-on-Trent, Handsworth, Smethwick, Grimsby, Derby, Wallasey, Tynemouth, or Newport (Mon.); in the other towns the highest zymotic mortality occurred in East Ham, Bournemouth, Aston Manor, Rotherham, Stockton-on-Tees, and Rhondda. The greatest proportional mortality from measles was recorded in Rotherham, Stockton-on-Tees, and Merthyr Tydfil; from "fever" in South Shields and Gateshead; from diphtheria in Willesden, Portsmouth, Bournemouth, Hanley, and Cardiff; from whooping-cough in East Ham, Plymouth, Aston Manor, Liverpool, Stockton-on-Tees, and Rhondda; and from "fever" in Walsall and West Hartlepool. 64 deaths from small-pox of persons belonging to London were registered last week, seven of persons belonging to West Ham, three to Tottenham, and one each to Walthamstow, Reading, and Swansea, but not one to any other of the 76 large towns. There were 1102 small-pox patients under treatment in the Metropolitan Asylums hospitals on Saturday, Feb. 8th, against 877, 870, and 1135 at the end of the three preceding weeks; 287 new cases were admitted during the week, against 213, 204, and 499 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2500, against numbers decreasing from 3137 to 2554 on the six preceding Saturdays; 227 new cases were admitted during the week, against 288, 299, and 226 in the three preceding weeks. The deaths in London referred to diseases of the respiratory organs, which had been 307, 357, and 375 in the three preceding weeks, further rose last week to 486, and were 32 above the corrected average. Influenza was certified as the primary cause of 40 deaths in London last week, against 23, 18, and 26 in the three preceding weeks. The causes of 81, or 1·4 per cent., of the deaths in the 76 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bolton, Salford, Newcastle, Cardiff, and 32 other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, St. Helens, Warrington, Preston, Sheffield, and South Shields.

## HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3 and 21·8 per 1000 in the two preceding weeks, further increased to 23·9 per 1000 during the week ending Feb. 8th, and exceeded by 3·3 per 1000 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 20·5 in Leith and 23·1 in Dundee to 24·3 in Edinburgh and 26·5 in Greenock. The 771 deaths in these towns included 23 which were referred to diarrhœa, 19 to measles, 17 to whooping-cough, 10 to scarlet fever, eight to diphtheria, five to "fever," and one to small-pox. In all 83 deaths resulted from these principal zymotic diseases last week, against 76 and 66 in the two preceding weeks. These 83 deaths were equal to an annual rate of 2·6 per 1000, which was 0·6 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 20 and eight in the two preceding weeks, rose again last week to 23, of which nine occurred in Glasgow, five in Dundee, four in Edinburgh, and three in Aberdeen. The deaths from measles, which had been 31 and 23 in the two preceding weeks, further declined to 19 last week, and included 16 in Glasgow and two in Greenock. The fatal cases of whooping-cough, which had been 11, 13, and 19 in the three preceding weeks, declined again last week to 17, of which 10 were registered in Glasgow, four in Paisley, and two in Aberdeen. The deaths from scarlet fever, which had been four and seven in the two preceding weeks, further rose to 10 last week, and included five in Glasgow, two in Aberdeen, and two in Greenock. The fatal cases of diphtheria, which had been five in each of the two preceding weeks, increased last week to eight, of which four occurred in Glasgow and two in Aberdeen. The deaths referred to different forms of "fever," which had been four, three, and three in the three preceding weeks, rose again to five last week, and included two in Glasgow and two in Edinburgh. The fatal case of small-pox was registered in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 128 and 141 in the two preceding weeks, further rose last week to 173, and were 15 in excess of the number in the corresponding period of last year. The causes of 21, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

## HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·9 and 22·7 per 1000 in the two preceding weeks, further rose to 23·8 per 1000 during the week ending Feb. 8th. During the past four weeks the death-rate has averaged 22·7 per 1000, the rates during the same period being 19·8 in London and 19·9 in Edinburgh. The 173 deaths of persons belonging to Dublin registered during the week under notice were eight in excess of the number in the preceding week, and included five which were referred to the principal zymotic diseases, against six, eight, and four in the three preceding weeks; of these, two resulted from whooping-cough, two from "fever," and one from diarrhœa. These five deaths were equal to an annual rate of 0·7 per 1000, the zymotic death-rate last week being 2·4 in London and 1·1 in Edinburgh. The 173 deaths in Dublin last week included 28 of children under one year of age and 45 of persons aged upwards of 60 years; the deaths of infants considerably exceeded the number recorded in the preceding week, while those of elderly persons showed a decline. Three inquest cases and five deaths from violence were registered; and 53, or nearly one-third, of the deaths occurred in public institutions. The causes of 14, or more than 8 per cent., of the deaths in Dublin last week were not certified.

## VITAL STATISTICS OF LONDON DURING 1901.

Complete statistics relating to sickness and mortality during the year 1901 in each of the cities and boroughs in the county of London are summarised in the accompanying table. The mortality figures relate to the deaths of persons actually belonging to the various metropolitan boroughs, and are the result of a complete system of distribution of deaths occurring in the institutions of London among the various boroughs in which the patients had previously resided. With regard to the notified cases of infectious diseases in London during 1901, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 8·9 per 1000 of the population, estimated at 4,543,757 persons in the middle of last year. In the three preceding years the rates had been 8·3, 9·3, and 7·7 per 1000 respectively. Among the various metropolitan boroughs the lowest rates were 5·3 in Chelsea, 5·8 in the City of Westminster, 5·9 in Kensington and in Hampstead, and 6·0 in Woolwich; the highest rates were 11·3 in St. Pancras and in Southwark, 11·4 in Hackney, 12·9 in Bethnal Green and in Bermondsey, and 13·1 in Holborn. The prevalence of small-pox in London during 1901 greatly exceeded that in any recent year; the number of new cases notified during the year was 1702, against 32, 29, and 88 in the three preceding years. This disease was proportionally most prevalent in the City of Westminster, St. Marylebone, St. Pancras, Holborn, Finsbury, and Bermondsey. The number of small-pox patients admitted into the Metropolitan Asylums hospitals during 1901 was 1788, and 666 remained under treatment at the end of the year. The prevalence

* Including membranous croup.

of scarlet fever during the year under notice was considerably greater than in the preceding year; the number of new cases notified being 18,390, against 16,894, 18,094, and 13,809 in the three preceding years. Among the various metropolitan boroughs scarlet fever was proportionately most prevalent in Finsbury, Shoreditch, Bethnal Green, Southwark, Bermondsey, Camberwell, and Deptford. During last year 14,959 scarlet fever patients were admitted into the Metropolitan Asylums Hospitals, against 12,480, 13,641, and 10,734 in the three preceding years; the number of cases under treatment, which had been 2883, 2797, and 2460 at the end of the three preceding years, had risen again to 3080 on Saturday, Dec. 28th, 1901. The prevalence of diphtheria during last year showed a slight increase over that recorded in the preceding year, 12,154 new cases being notified, against 13,692 and 11,994 in the two preceding years. The greatest proportional prevalence of this disease occurred in Fulham, St. Pancras, Hackney, Bethnal Green, Poplar, Camberwell, and Deptford. The Metropolitan Asylums Hospitals contained 1369 diphtheria patients at the end of the year, against 1674 and 1343 at the end of the two preceding years; the new cases admitted, which had numbered 8777 in the preceding year, rose to 9090 during 1901. Enteric fever showed a considerably diminished prevalence last year, only 3195 cases being notified, against 4456 and 4306 respectively in the two preceding years; among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, Hackney, Bethnal Green, Stepney, Poplar, and Bermondsey. The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals during 1901 was 1480, against 1116, 1835, and 2074 in the three preceding years; 195 es remained under treatment at the end of December gainst 406 and 403 at the end of the two preceding Erysipelas showed the highest proportional prevalence last year in Hackney, Holborn, Finsbury, Bethnal , Stepney, Southwark, and Bermondsey. The 251 fied cases of puerperal fever showed an increase of 14 er the number recorded during 1900; 33 cases belonged to slington, 19 to Camberwell, 16 to Hackney, 16 to Stepney, 14 to Lambeth, 14 to Wandsworth, 13 to Paddington, and 13 to St. Pancras.

During the year under notice the deaths of 77,663 persons belonging to London were registered, equal to an annual rate of 17·1 per 1000, against 18·5, 19·6, and 18·7 in the three preceding years, 1898, 1899, and 1900; the average rate in the 10 years 1891–1900 being 19·2 per 1000. In the various metropolitan boroughs the lowest death-rates were 10·7 in Hampstead, 13·0 in Lewisham, 13·2 in Stoke Newington, 13·4 in Wandsworth, 14·3 in Paddington, and 14·6 in Woolwich; and the highest rates 20·3 in Bethnal Green, 20·9 in Stepney and in Bermondsey, 21·4 in Finsbury, 21·5 in Southwark, and 21·9 in Shoreditch. Taking the five groups of boroughs the rates of mortality during 1901 were 15·7 in the west, 16·0 in the north, 16·7 in the south, 20·7 in the east, and 20·8 in the central. To the principal zymotic diseases 10,107 deaths were attributed during the year; of these, 3900 resulted from diarrhœal diseases, 1952 from measles, 1604 from whooping-cough, 1330 from diphtheria, 584 from scarlet fever, 508 from different forms of "fever" (including four from typhus, 497 from enteric fever, and seven from simple continued fever), and 229 from small-pox. These 10,107 deaths were equal to an annual rate of 2·22 per 1000, against 2·84, 2·52, and 2·24 in the three preceding years. Among the various metropolitan boroughs the zymotic death-rates ranged from 1·02 in Hampstead, 1·06 in the City of London, 1·28 in Stoke Newington, 1·31 in Chelsea, 1·34 in City of Westminster, 1·51 in Woolwich, and 1·55 in Wandsworth, to 2·86 in Hammersmith, 2·88 in Bethnal Green, 2·90 in Bermondsey, 2·99 in Shoreditch, 3·02 in Southwark, and 3·04 in Poplar. The 229 fatal cases of small-pox showed an excess of 186 over the corrected average number in the 10 preceding years; the greatest proportional mortality from this disease occurred in Hammersmith, City of Westminster, St. Pancras, Holborn, Stepney, Southwark, and Bermondsey. The 1952 deaths referred to measles were 707 below the average number in the 10 preceding years; among the various metropolitan boroughs the disease was proportionally most fatal in Shoreditch, Bethnal Green, Stepney, Southwark, Bermondsey, and Battersea. The 584 fatal cases of scarlet fever showed a decline of 275 from the corrected decennial average, the highest death-rates from this disease being recorded in Finsbury, Shoreditch, Bethnal Green, Southwark, Bermondsey, and Camberwell. The 1330 deaths referred to diphtheria were 918 below the average number in the 10 preceding years; among the various metropolitan boroughs this disease was proportionately most fatal in St. Pancras, Islington, Hackney, Bethnal Green, Poplar, and Camberwell. The 1604 fatal cases of whooping-cough showed a decline of 679 from the corrected average number; this disease showed the highest proportional fatality in Hammersmith, Fulham, Shoreditch, Poplar, Southwark, and Battersea. The 508 deaths referred to different forms of "fever" were 120 below the average number in the 10 preceding years; among the various metropolitan boroughs the fever death-rate was highest in Fulham, Holborn, Bethnal Green, Stepney, Poplar, and Bermondsey. The 3900 deaths from diarrhœal diseases exceeded the average number by nearly 400; the greatest proportional mortality from these diseases occurred in Fulham, Finsbury, Shoreditch, Poplar, Southwark, and Battersea. In conclusion, it may be stated that the mortality in London during 1901 from the zymotic diseases in the aggregate was 17·1 per cent. below the average.

Infant mortality in London last year, measured by the proportion of deaths under one year of age to registered births, was equal to 148 per 1000, against 166, 166, and 158 in the three preceding years. The rates of infant mortality in the various metropolitan boroughs ranged from 104 in Hampstead, 107 in St. Marylebone, 115 in Stoke Newington, 124 in Holborn, and 129 in Lewisham and in Woolwich; the highest rates were 165 in Poplar, 168 in Hammersmith and in Southwark, 169 in Bermondsey, 175 in the City of London, and 197 in Shoreditch.

## THE SERVICES.

### ARMY MEDICAL SERVICE.

Surgeon-General Henry S. Muir, C.B., is placed on retired pay. Dated Jan. 1st, 1902.

### ROYAL ARMY MEDICAL CORPS.

Captain J. Grech will shortly re-embark for South Africa.

Lieutenant J. H. Robinson is appointed to the charge of the Station Hospital at Fort Attock.

Lieutenant-Colonel Christopher William Moore Keys is placed on retired pay. Dated Dec. 26th, 1901.

The undermentioned Captains to be Majors (dated Feb. 1st, 1902:—William Thomas Mould, Alfred William Bewley, Charles Alfred Stone, Herbert Edmond Winter, and Lewis Way.

The undermentioned Lieutenants to be Captains (dated Jan. 28th, 1902): Harold Percy Waller Barrow, John Edward Hodgson, Alec Lauriston Scott, Lionel Edmund Longworth Parker, James Geoffrey Gill, Matthew Henry Gregson Fell, Gerald Hamilton Goddard, William Bertram Winkfield, Thomas Campion Lauder, Jonas William Leake, John William Hobart Houghton, Duncan Edward Curme, Herbert Stockley Taylor, George Mills Goldsmith, Richard Harte Lloyd, David Harvey, John Macfarl Sloan, Henry Evered Haymes, Francis John Brakenrid George Constantine Phipps, Nathaniel John Crawford tterford, Gilbert John Anthony Ormsby, Harry Dixo Packer, Lawrence Humphrey, Robert Stuart Rodger, William Watson Scarlett, Horace Kemp Palmer, Arthur O Bird Wroughton, and Frank Ashe.

Lieutenant Joseph R. Welland is seconded f service in Somaliland. Dated Jan. 3rd, 1902.

### VOLUNTEER CORPS.

*Rifle*: 1st Volunteer Battalion the North berland Fusiliers: Surgeon-Lieutenant H. Dickie to be Surgeon-Captain. 4th Volunteer Battalion the East Surr Regiment: Surgeon-Lieutenant C. J. Martin to be Surgeon-Captain. 1st Nottinghamshire (Robin Hood): Surgeon-Lieutenant R. H. Cordeux to be Surgeon-Captain. 1st (Inverness-shire Highland) Volunteer Battalion the Queen's Own Cameron Highlanders: Brigade-Surgeon-Lieutenant-Colonel O. Grant is seconded whilst serving on the staff of a Volunteer Infantry Brigade.

### ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The London Companies: Captain F. J. L. Warwick is appointed Transport Officer to the Division.

## ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING THE YEAR 1901.

* Including membranous croup

Again, from the patient's point of view it is much less distress to have the chest-piece of a binaural lightly on one's tender chest than to have a man pressing at the end of a wooden instrument. In this I can speak from experience of the chest end of the stethoscope. I am sorry Dr. Syers's criticisms are so belated; 20 years ago they would have been almost in time to have influenced perhaps a few men to avoid these "new-fangled toys," but, alas, the times move, and the obvious thing to do is to teach students to diagnose with such imperfect instruments as we have nowadays.

I am, Sirs, yours faithfully,
Feb. 10th, 1902. A. CHARPENTIER, M.D. Durh., D.P.H.

## SUPERANNUATION OF POOR-LAW OFFICERS.

*To the Editors of* THE LANCET.

SIRS,—The actuarial report on the Poor Law Superannuation Bill (Ireland) has now been made public. It is based to a considerable extent on assumptions. First, that the salaries of poor-law officials are subject, as a matter of course, to a periodical and substantial increase. The past history of salary increments shows that they are rarely increased, and therefore the claims upon the pension fund would fall much below the sum named by the actuary. Secondly, that poor-law officials do not resign or otherwise cease to hold office, or that they do not die before reaching the pensionable age of 65 years. Probably Dr. Howell had no data upon which to base a reliable report in this respect. They are facts nevertheless, and must have an important bearing on the average payments from the fund. The percentage deductions in the English Act of 1896 embodied in the present Bill were based upon the percentages adopted by large public bodies in England for the superannuation of their officers—e.g., the Corporation of London, the Liverpool Corporation, the North-Western Railway, the North-Eastern railway, the School Boards, the Metropolitan Board of Works, and the London County Council. It was not expected that the fund created by the deductions from income would at first be sufficient to meet all claims. There was, however, reason to believe, from the experience of other similar funds under the management of the public bodies mentioned, that the percentages would be found sufficient more than to cover the proportion of the superannuation fund which Poor-law officers should be asked to bear; more particularly so having regard to the equitable claim already possessed by some of these officers under existing Acts. The actuarial report further states that in the event of the Bill becoming law it was absolutely necessary that the fund should be a national and not a union fund. This would be a most advisable arrangement, inasmuch as Clause 4 of the proposed Bill provides that all service, whether continuous or not, shall be aggregated.

I am, Sirs, yours faithfully,
Irish Medical Association, Feb. 8th, 1902. THOMAS GICK.

## FUNERALS IN INCLEMENT WEATHER.

*To the Editors of* THE LANCET.

SIRS,—In inclement weather might not all the Funeral Service, except the words of committal and the grace, be said in the church or cemetery chapel?

I am, Sirs, yours faithfully,
F. LAWRENCE,
Honorary Secretary, Funeral Reform Association.
Westow Vicarage, York, Feb. 10th, 1902.

## PROPOSED WATER BOARD FOR LONDON.

*To the Editors of* THE LANCET.

SIRS,—The very important remarks contained in the leading article on "The Metropolitan Water-supply," in THE LANCET of Feb. 8th, p. 384, cannot but prove valuable to all concerned. It appears to me, therefore, that now is the time that the present position and condition of the mains and service pipes now used in carrying the water from the various companies' reservoirs to the users (especially in central London) should be seriously considered, because (beyond the question of loss by leakage underground from unsound pipes, joints, valves, connexions, &c.) there cannot be much doubt that if an absolutely pure sterile water should ultimately be turned into the present system of distributing mains and service pipes it would be rendered far more unwholesome and unfit for dietetic use than the worst of the present waters used in the metropolis. Provision should be made for a new system of mains and services for wholesome waters, carried in properly constructed and well-ventilated subways, and thus safe from the filthy surroundings in which all the present mains and services are buried.

Should the new water-supply be separated in the manner I propose not only would an enormous amount of underground loss be saved, but also a very large amount of inconvenience.

I am, Sirs, yours faithfully,
*Ebury-street, S.W., Feb. 8th, 1902.* D. T. BOSTEL, Sen.

---

## TWO CASES OF SOLID ABDOMINAL TUMOUR WITH ASCITES.

*To the Editors of* THE LANCET.

SIRS,—Dr. T. W. Eden in his clinical lecture on "Two Cases of Solid Abdominal Tumour with Ascites," published in THE LANCET of Feb. 8th, p. 349, mentions that "an extended search in text-books and monographs and in the transactions of obstetrical societies has only revealed one such case, recorded by Thomas Keith." Dr. Eden possibly has overlooked a case reported by me in the *British Medical Journal*, Dec. 21st, 1900, p. 1773: "Notes on a Case of Profuse Hydroperitoneum complicating Uterine Fibroids." I am, Sirs, yours faithfully,
A. C. BUTLER-SMYTHE, F.R.C.S. Edin.
Brook-street, W., Feb. 12th, 1902.

---

## DIFFICULTIES UNDER THE INFECTIOUS DISEASES (NOTIFICATION) ACT.

*To the Editors of* THE LANCET.

SIRS,—Some days ago I, as medical officer of health, received a notification from a medical practitioner notifying that E. R. was suffering from diphtheria. On the form, at foot, was written, "This child is suffering from scarlatina as well as diphtheria, see next form." The next form inclosed with the other was a notification that E. R. was suffering from diphtheria. Would you be good enough to let me know whether the notifier is entitled to two fees? Am I to make a double entry as regards the child? If so, I have apparently two cases, instead of one, ill at the same time.

I am, Sirs, yours faithfully,
Jan. 30th, 1902. H. W.

⁂ The practitioner notifying is entitled to a fee for each disease notified, albeit the two diseases here in question existed simultaneously in the same individual. Had, say, a month elapsed between the two notifications "H. W." would have had no hesitation as to his line of action, and there is no time-limit laid down by the statutes. Possibly, the present law in this particular may eventually be modified, seeing that the control of the patient is the chief object to be attained by notification; but as the law now stands two fees can be claimed. We assume, of course, that "H. W." has no reason to question the *bonâ fide* nature of the notifications. A double entry should be made and an explanatory note appended. We suppose that the second form was a notification of scarlet fever, and not, as the letter reads, of diphtheria.—ED. L.

---

## LABELS AND LIABILITIES.

*To the Editors of* THE LANCET.

SIRS,—So far as the law is concerned little doubt can be raised in the matter which you discussed last week under this heading (p. 387). Certain articles are scheduled as poisons and these may only be handed to the public on certain conditions. Moreover, they may only be so handed either by qualified medical practitioners or by chemists registered under the Pharmacy Act. For one set of poisons these conditions are that the person wishing to obtain the drug in question shall be either personally known to the person dispensing the drug or

### VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

Surgeon-General Taylor, C.B., will present medals to the members of this school who served in the Rhodesian Field Hospital at the London Scottish headquarters, Buckingham-gate, S.W., at 9 P.M. on Monday, Feb. 17th.

### VOLUNTEER MEDICAL STAFF CORPS.

The annual distribution of prizes to members of the Volunteer Medical Staff Corps will take place at the headquarters, 51, Calthorpe-street, London, W.C., on Saturday, March 1st, at 8 P.M., when Surgeon-General Taylor, C.B., will preside. A dance will follow the distribution of prizes.

### SOUTH AFRICAN WAR NOTES.

Lieutenant A. O. B. Wroughton, R.A.M.C., is reported progressing favourably and out of danger at Queenstown (Feb. 9th).

Civil Surgeon Bensusan is reported out of danger (Feb. 7th).

Civil Surgeon Fort is reported slightly worse (Feb. 7th).

### AFFAIRS IN SOUTH AFRICA.

The purely military news from South Africa during the past week is somewhat mixed but is indicative of increased activity on both sides with the balance of advantage, on the whole, on the side of the British. The "wearing down" process as regards the Boer forces has been going on, and still seems to be going on at an accelerated pace, and that appears to sum up the situation. The main object of the carefully designed operations for surrounding and capturing that redoubtable tactician De Wet and his force in the Heilbron and Kroonstadt district distinctly failed. De Wet, taking advantage of a dark night, stampeded a herd of cattle against a part of the blockhouse line, broke through it, and made his escape. The War Office return of casualties reported since the beginning of the war up to and including last month shows that the total reduction of the military forces in South Africa, including deaths from all causes, missing, prisoners, and invalids who have been discharged from the service as unfit, amounts to 25,305, counting officers, non-commissioned officers, and men. As regards the forces now in the field it will be seen by the published sick returns that there is still a good deal of enteric fever, but that the health of the troops, speaking generally, is satisfactory.

### THE MILITIA AND VOLUNTEER MEDICAL STAFF CORPS: CHANGES IN DESIGNATION.

The King, in consideration of the valuable services rendered by the Militia Medical Staff Corps and Volunteer Medical Staff Corps during the war in South Africa, has approved the following changes in the designation of the corps and in the titles of the officers:—The Militia Medical Staff Corps will be known as the Royal Army Medical Corps (Militia), and the Volunteer Medical Staff Corps as the Royal Army Medical Corps (Volunteers). The titles of the officers will be altered from Honorary Commandant and Honorary Surgeon-Colonel to Honorary-Colonel; Honorary Surgeon-Lieutenant-Colonel Commandant to Honorary Lieutenant-Colonel Commandant; Surgeon Lieutenant-Colonel to Lieutenant-Colonel; Surgeon-Major to Major; Surgeon-Captain to Captain; and Surgeon-Lieutenant to Lieutenant.

### THE VICTORIA CROSS.

The King has signified his intention to confer the decoration of the Victoria Cross on the undermentioned officer for conspicuous bravery in South Africa:—

Surgeon-Captain T. J. Crean, 1st Imperial Light Horse.

During the action with De Wet at Tygerskloof, on Dec. 18th, 1901, this officer continued to attend to the wounded in the firing line, under a heavy fire at only 150 yards range, after he had himself been wounded, and only desisted when he was hit a second time and, as it was at first thought, mortally wounded.

### SOLDIER CHIROPODISTS.

The issue of the Army order about the appointment of soldier chiropodists has been followed, we understand, by the publication of an official "Manual of Chiropody," which we have not yet seen. Such a manual, giving plain advice on the causes, nature, and treatment of the common ailments of the feet to which soldiers are exposed, should be very serviceable. The Americans, during their big war of rebellion, were the first, we believe, to employ chiropodists in the army.

## Correspondence.

"Audi alteram partem."

### "WHAT'S WHAT."

*To the Editors of* THE LANCET.

SIRS,—In a recent publication called "What's What" there is, I understand, a paragraph indicating various medical men by name as consultants, with my name among the number. I should have thought that it was quite unnecessary for me to say that I had nothing whatever to do with such a paragraph and was, indeed, quite ignorant of its existence until the other day. To my surprise, however, a paper called the *Medical Times and Hospital Gazette*, of the existence of which I was also unaware, was sent to me last week containing a most offensive paragraph which insinuates very pointedly that it is by no means certain that those whose names are mentioned in "What's What" are quite innocent in the matter. I wrote to the editor of "What's What" asking him to withdraw my name from his paragraph, and I inclose my letter and his reply and also a letter which I sent to the *Medical Times and Hospital Gazette.*

I am, Sirs, yours faithfully,

Feb. 11th, 1902. W. WATSON CHEYNE.

[INCLOSURES.]

*To the Editor of "What's What."*

Feb. 9th, 1902.

DEAR SIR,—My attention has been called to a paragraph in "What's What" in which a list of medical men is given containing, among others, my name. I feel sure that you did not at all realise how such a paragraph would affect those whose names are mentioned, otherwise you would not have inserted it. I presume your object in introducing it was that just as you tell elsewhere what people should do or see so you want to guide them if they are ill. If that was your object it would entirely fail, because patients, if they are wise, ask their family medical man whom they should consult and would not be at all guided by a paragraph in a book or newspaper. On the other hand, those whose names are mentioned in this way may suffer irreparable damage as the result. While the better class practitioners would, of course, assume that such a paragraph was inserted entirely without our knowledge or consent and would know that we would not have anything to do with such an advertisement, there are, I am sorry to say, men in our profession, as in every other, with jealous and dirty minds who would assume that we were not innocent in the matter, and would employ this occurrence to blacken our characters in every way possible. I need only refer you to an article in yesterday's issue of the *Medical Times and Hospital Gazette* as an example of this. For these reasons I would strongly advise you to suppress this paragraph, and in any case I would beg of you to cut my name out of the list.

Yours faithfully,

W. WATSON CHEYNE.

*Reply from the Editor of "What's What."*

MY DEAR MR. WATSON CHEYNE,—With much that your letter contains I heartily agree, and I will gladly do as you ask with regard to your own name and in all probability with regard to the whole paragraph. I cannot, however, agree with you as to its being so great a crime to inform the public on these matters—nor that one's "family medical man" is in all cases the most fitting person to advise. How about the cases also where one has no "family medical man"? What is to happen then? The intention and the limitations of my paragraph in the appendix are very clearly stated and nobody in their senses could read it and not see that its origin was in personal opinion and experience and not in the desire to advertise anybody. In this troublous and troubling world, however, the best motives are liable to misrepresentation, and breaches of etiquette even by a layman are apparently "the unforgivable sin." I shall not again hurl myself so wantonly against the 'footstool of justice" to serve the public; in this case they will have to look elsewhere for "what's what."

Meanwhile I could wish that all who differ from me would express themselves with your courtesy and moderation.

I have not seen the paragraph to which you allude in the *Medical Times*, but I can guess its tenor.

Very truly yours,

Feb. 10th, 1902 HARRY QUILTER.

*To the Editor of the "Medical Times and Hospital Gazette."*

Feb. 9th, 1902.

SIR,—With reference to your paragraph on p. 85 in your issue of yesterday I do not know which is most offensive—viz., the original paragraph or the one in your issue. Whatever the object of the editor of "What's What" may have been what he has done has, I am sure, been in ignorance In your paragraph, however, you imply the possibility on our part of some knowledge of, or complicity in, this publication, an insinuation which is most offensive and absolutely unwarrantable. It surely might have occurred to you that men in the position of those whose names are mentioned would not lower themselves to such an extent as to have either directly or indirectly incited such a statement or that they had any knowledge of it beforehand. If you can indicate how such occurrences can be avoided or how the matter can be remedied I shall be most grateful to you, but I resent most strongly that you should have in the faintest degree implied that I have anything whatever to do with the matter. I am not aware that I have ever done anything which should make you think that that was at all possible.

Yours faithfully,

W. WATSON CHEYNE.

reduction this week in the number of deaths throughout India. The figures, however, are still very high, being 9204 for the whole of India—a reduction on the total of the previous week of 1164. In the Bombay Presidency the deaths have fallen from 4797 to 3510, and in the Punjab there has been a slight reduction also—viz., from 2662 to 2379. On the other hand, there has been a further increase in the North-West Provinces and in Bengal, and there is a decided rise in the mortality both in the cities of Bombay and Calcutta. For the latter city there are recorded 50 deaths, against only 22 for a fortnight ago, and rats are reported to be found dead and dying in various parts. In Bombay city there were 250 deaths from plague. There is little doubt therefore that the two chief cities of India are threatened with fresh outbreaks. With reference to the Punjab it is unfortunate to notice that the Tahsils of Nawashahr and Gaishaukar in the Jullunder and Hoshiapur districts, which were thoroughly inoculated in 1899–1900, show no less than 5373 cases and 2427 deaths during the last three months. Orders have been issued for the resumption at Simla of the plague precautionary measures that were in force during last summer. Disinfecting gangs are to be re-formed and surveillance over new arrivals is to be re-established by the immediate reopening of the road and medical inspection posts at Kalka, Tara, Devi, and Taur.

India is still oppressed by the famine which is again increasing. The total number of persons receiving relief [illegible] now 181,651. The Bombay Presidency is the chief sufferer, but 6430 persons have had to be relieved in Rajputana.

No announcement has yet been made regarding an increase in the cadre of the Indian Medical Service, which is understood to have been under discussion for some years back, but it may be noted that the Secretary of State for India has been asked to admit three more candidates, making 20 in all, to the next examination for the Indian Medical Service.

I understand that Sir Francis Lovell, K.C.M.G., who is visiting India on behalf of the London School of Tropical Medicine, has been very successful in obtaining subscriptions, and that some £10,000 have been already remitted. Bombay has answered the appeal with great warmth but very little has been got from Calcutta.

Jan. 24th.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *Manchester and Salford Hospital for Diseases of the Skin: the Finsen Light Process.*

THE Lord Mayor presided at the annual meeting of the friends of the Manchester and Salford Hospital for Diseases of the Skin on Feb 4th Among the 33,356 attendances of patients 6633 were for the "light" treatment Many came from neighbouring towns and a few serious cases were treated as in-patients. It is satisfactory to learn that in consequence of inquiries as to the position and means of patients "there had been a considerable falling off in the attendance of unsuitable persons as patients." The committee reported a great need for an increase of beds, at least 20 or 25 being required The medical report made special reference to the treatment of lupus, for which primarily the Finsen light and Roentgen ray department was started last year. The cases now being treated include not only lupus and the other tuberculous affections, but also forms of cancerous and rebellious ulceration. The report states that though it is too early to judge of the final results, the improvement in cases hitherto rebellious to all treatment has been so encouraging that thorough and permanent cure may be hoped for. Being almost painless the patients now coöperate in the treatment as they never have done before. Dr. H. A. G. Brooke hoped that they would soon have apparatus which would expedite the Finsen process and Dr. R. B. Wild stated that very promising results had been obtained by the Roentgen rays "in cases that were practically forms of cancer." Dr. J. Dreschfeld, in moving a vote of thanks to the chairman, said that there was no large town with so little accommodation for skin diseases. There was an immediate demand for 20 beds, and he thought that 50 should be provided.

### *School Ventilation and Lamp Accidents.*

The committee of the Manchester and Salford Sanitary Association has been in communication with the Education Department as regards the ventilation of schools and, on the invitation of Sir John Gorst, has submitted the draft of a circular for issue to managers and inspectors of schools. In addition to suggestions as to the ventilation of the schools the circular recommends that instruction should be given to the children on the value of ventilation both at school and in their homes, and that the ventilation should be examined when there is much "school illness" in the classes. At the last meeting of the committee a report was received from Mr. W. Thomson, analytical chemist, on nine lamp explosions investigated between November, 1900, and the end of December, 1901. Seven out of the nine lamps were of a dangerous type. The flash-points of the four samples of oil tested lay between 83° and 90° F. Since these investigations were commenced in 1896 up to the present, "no sample of oil having a flash-point at or above 100° F. had been found to be used in a lamp which exploded."

### *Ventilation of Manchester Sewers.*

In April, 1901, the Paving, Sewering, and Highways Committee of the Manchester City Council, in consequence of several accidents, asked for, and has been furnished with, a comprehensive and detailed report on sewer ventilation. The city surveyor recommended systematic ventilation, consisting of upcast shafts in suitable positions with surface ventilators as inlets for fresh air. He also recommended that the plant used for treating manufacturers' refuse should be open to official inspection at any time, and that where such refuse contained chemicals which would become of an explosive or dangerous character on entering the sewers they should be rigorously excluded. As there are 1700 miles of sewers the committee, of which Dr. Dearden is chairman, at its last meeting appointed a sub-committee of eight to go into the whole matter.

### *"Methods of Barbarism."*

An inquest held yesterday by the City Coroner on the case of a woman in Gorton who died from acute pneumonia throws some light on the methods of agents of cottage property in dealing with those who are behind with their rent. This poor woman, who was tuberculous, took to her bed on Feb. 1st, and remained there till the 4th when the chimney was blocked up by order of the landlord's agent. No fire could be kept in the house, but she stayed there till her death on the 8th. It can be imagined what discomfort and misery this proceeding would cause during the unusually severe weather experienced in this district, and how it would render her poor chance of recovery almost hopeless. No medical man was called in, because the man with whom the woman had lived for three years had no money, and "didn't think" of calling in the parish medical officer. The post-mortem examination showed extensive tubercle in both lungs and pneumonia of the left lung, and in face of this the coroner did not think the jury could bring in a verdict of manslaughter, but he characterised the proceedings of the agent as "most brutal." The verdict was "in accordance with the medical evidence," and the jury thought that the agent, the "property-repairer," and the paramour should be censured, "the latter for not calling in a doctor." Such occurrences as the above should induce those who seem to look only abroad for methods of barbarism to consider whether our processes for the recovery of rent may not be open to improvement.

### *Arsenical Beer Poisoning.*

The dire effects of arsenical beer have not entirely ceased. A middle aged man was admitted on Jan. 15th to hospital at Halifax suffering from arsenical beer poisoning. His illness ended fatally, and at the inquest held on Feb. 8th a verdict was returned of "Death from pneumonia, accelerated by arsenical poisoning."

### *Testing for Arsenic.*

At the meeting of the Manchester section of the Society of Chemical Industry, held on Feb. 8th, Dr. Gerland explained his process for the estimation of minute quantities of arsenic in beer. A solution of bismuth is first added to the beer, and is then precipitated by means of sulphuretted hydrogen. The arsenic is carried down with the precipitate, and is then dissolved out by means of carbonate of ammonia. The solution of bismuth must, of course, be free from arsenic. The separated arsenic is then estimated in the Marsh apparatus. The chairman, Dr. Grossman, said that the Manchester committee appointed to investigate the question of arsenic in beer had done nothing.

Feb. 11th.

shall be introduced by some other person so known. In the majority of instances, of course, this introduction is really represented by the presentation of a prescription signed by a qualified medical man For the other set of poisons, those included under Part II of the section of the Pharmacy Act in question, the condition is that the purchaser on purchasing the drug shall sign a certain form kept by the vendor In a section of the "Act to Amend the Pharmacy Act" particular statement is made that all these conditions do *not* apply to poisons supplied by a qualified medical man provided that he complies with one other condition This other condition justly excited the surprise of your correspondent last week The attention of the General Medical Council was called to the subject recently owing to the revelation of a state of affairs which was apparently very common in Scotland but which does not probably hold good to a large extent in England I refer to the practice of maintaining a "doctor's shop" or surgery, as it was often called from which a man legally qualified neither medically nor as a chemist dispensed all kinds of drugs to the patients of the medical man owning the "shop" Obviously, when the prescription dispensed happened to contain a scheduled poison the dispenser was committing a breach of the law with regard to poisons Whether he fulfilled the conditions to which I have referred above or not he still committed a breach of the law, because in the eye of the law he was from his unqualified state a man not permitted to dispense drugs scheduled as poisons The decision of the General Medical Council in the matter is stated in the formal account of the sitting of Saturday, Nov 30th 1901, in these words —

> Whereas it has come to the notice of the Council that medical practitioners who keep medical halls or open shops in which scheduled poisons or preparations containing scheduled poisons were sold to the public have been accustomed to leave in charge of such halls or shops assistants who are not legally qualified to sell scheduled poisons to the public and have thereby enabled such unqualified assistants to sell scheduled poisons and so to commit breaches of the law the Council hereby give notice that any registered medical practitioner who is proved to have so offended is liable to be judged guilty of ' infamous conduct in a professional respect and to have his name erased from the Medical Register

It seems to me that the Council could have ruled in no other fashion and that so far, the general practitioner, on whose behalf your correspondent writes, has no cause for complaint in the action of the General Medical Council

I am, Sirs, yours faithfully,

M D

Feb 8th

---

*To the Editors of* THE LANCET

SIRS,—*Apropos* of the annotation in THE LANCET of Feb 8th, p 387, entitled "Labels and Liabilities," it is now a very common custom among medical men to have their names, degrees (whether medical or otherwise), and the hours at which they are "at home" for consultation printed at the top of their prescription slips

If the law does happen to require exactly the kind of thing to which the General Medical Council would take vigorous objection—viz , that a medical man's name should under certain circumstances be upon the label of the bottle containing his compound—is it more of an advertisement than having his name, qualifications and hours of consultation upon his prescription slips?

As a matter of fact the prescription slip will probably be a more advantageous advertisement, as it will pass through more hands When the patient goes home it will be shown to the relatives and discussed and some popular "Domestic Medicine' will be turned up to see what the various ingredients are being given for It will then be shown to any neighbours and friends who may have looked in to inquire after the suffering one Finally it will reach the chemist, who will explain in popular language the uses and actions of the drugs prescribed

We are so accustomed to these prescription slips that we never regard them as advertisements, but simply think it is convenient for our patients to have a reminder of the most convenient hour at which to consult the busy man, and in their interests we must uncomplainingly bear any reproach which may be laid upon us for what might appear to others not conversant with professional matters to be an advertisement. And, indeed, should a patient be impressed with the skill of the practitioner it is also convenient for him, or her (females are most strongly recommended by the writer for this game), to be able to mention the respective hours when his, or her, physician is at home," if he, or she, happens to recommend him to a friend perhaps a dissatisfied patient of another practitioner

For my own part, I cannot see why a dispensing practitioner should not add his consultation hours to his labels also keep me right if I go wrong—but there seems little difference Presumably a dispensing practitioner does not have prescription slips and it seems, at first sight at all events, unfair that his non dispensing *confrère* should alone be able to let the general public know his hours "at home" The exigencies of the case might possibly be met, and the General Medical Council not over flurried, by the dispensing practitioner using prescription slips to wrap his medicine bottles up in

The whole subject is terribly distasteful to

Feb 10th 1902 AN UNCOMPLAINING BUSY MAN

# NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT )

*The Spread of the Plague —Increase of the Famine —The Malaria Convention —The St John Ambulance Association in Calcutta*

THE deaths from plague throughout India last week reached the total of 10,368 This is 502 more than in the previous week and compares very unfavourably with the small total of 2839 for the corresponding week of last year The Bombay Presidency returns 4797 deaths, the Punjab 2662 the Madras Presidency 586, the Bengal Presidency 462, the North West Provinces and Oudh 685, Mysore State 636, Hyderabad State 50, and Kashmir 192 In the cities the deaths were Bombay, 234 , Calcutta 36 , and Karachi, 70 Poona city is not reported but local reports show that plague is developing rapidly and the deaths there are over 50 a day The present features of the epidemic are its steady extension in the Madras Presidency, where at this time last year only 25 deaths from plague occurred, and the serious headway which it is making in the Punjab, where three months ago only 90 cases were returned , it is also increasing in Bengal There is a decided jump in the figures for Calcutta An outbreak has occurred at Lahore for the first time but active steps are being taken and inoculation is being pushed vigorously In Jullunder city also an indigenous case has occurred To compensate for increase elsewhere the disease is declining in virulence in the Bombay districts, although it is developing again in Bombay city

The famine is again worse and 17,000 people have been added to those receiving relief who now amount to 158 000, the figures being Bombay and Said, 94,500 , Baroda State, 33 000 , Bombay Native States 22,000 , and the Punjab, 3000 This has been largely due to the abnormal rainfall , for India generally the average is about 40 inches, but it varies from 10 inches in the North West Provinces to 100 inches in Assam The west of India received much less than its normal amount of rain this year, Karachi, Mooltan, Hyderabad, Quetta, and Mount Abu getting only about half their average

The Malaria Convention at Nagpur has been a great success, not only in attendance but in the interest of the papers read The chief of these were on the Classification of Anopheles, by Captain Glen Liston , on the Endemicity of Malaria, by Dr Christopher, who also contributed a paper on the Prevalence of Anopheles , on the Examination of the Blood by Captain Rogers , and on the Means of Preventing Malaria by Captain G I Birdwood

The St John Ambulance movement seems to be making headway in India Classes are being held among natives as well as among Europeans in several cities and instruction is being given by civil surgeons to the police A successful distribution of over 200 certificates recently took place in Calcutta where 13 classes have been already held and amongst them three large classes of Mahomedan students There seems to be a difficulty in exciting interest among the Hindoos which is apparently due to the influence of caste There appears to be a general opinion that while classes might be got together it is very doubtful whether the instruction would ever be put in practice Those who have lived in India will understand the inhibiting influence of caste as much in this matter as in others

*The Plague Epidemic —Further Increase of the Famine —Increase of the Indian Medical Service —Subscriptions for the London School of Tropical Medicine*

IN consequence of the decline of the epidemic of plague in parts of the Bombay Presidency there has been a

In medicine, Dr. James A. Lindsay (Belfast) and Dr. J. F. O'Carroll (Dublin); in ophthalmology, Dr. A. W. Sandford (Cork) and Dr. Louis Werner (Dublin); in midwifery, Dr. John W. Byers (Belfast) and Dr. A. J. Smith (Dublin); in medical jurisprudence, Dr. Charles Y. Pearson (Cork) and Mr. Antony Roche (Dublin); in materia medica, Dr. Martin Dempsey (Dublin) and Professor W. Whitla (Belfast); in physiology, Dr. W. H. Thompson (Belfast); in pathology, Dr. E. J. McWeeney (Dublin) and Dr. J. Lorrain Smith (Belfast); and in sanitary science, Sir C. A. Cameron (Dublin). It was agreed to postpone the question of appointing extern examiners until the May meeting.

### *The University Question.*

On Feb. 9th the Lenten pastoral of his Eminence Cardinal Logue (the head of the Irish Catholic Church) was read in the Catholic churches in Armagh. Referring to the questions of a Catholic University and of temperance the Cardinal said that if the Catholics of Ireland were to bind themselves together, even for one year, and to enter into a "solemn covenant" to dispense with drink and to pay into a common fund what is usually expended on it, the amount would establish and endow a university which would be the admiration of Europe.

### *Preventive Inoculations of Anti-diphtheritic Serum.*

AT the meeting of the Academy of Medicine held on Jan. 28th M. Netter gave some extremely interesting statistics about inoculations of Roux's serum which were given at the Trousseau Hospital not for the object of treating diphtheria but as a preventive. When first the serum began to be used in this manner certain medical men took great exception to the practice. They said that it simply gave diphtheria to those who had none, and sundry unfortunate sequelæ of the use of the imperfect serum of the early period were collected together and exploited by the enemies of serotherapy. Then it was said that the inoculations did no good. The answer to this was that too small a dose was given. As a matter of fact at least five cubic centimetres of serum—i.e., 1000 units—must be given. Sometimes, too, the injection was not given early enough or infection took place before immunisation was well established. To-day, however, the value of the practice is proved and M. Netter has never found preventive inoculations given to children in danger of diphtheria to cause any unpleasant complications. Moreover, a study of comparative statistics enables a calculation to be made of the number of children who would have fallen victims to diphtheria had the preventive action of the serum not intervened. It is possible to foresee the time when inoculation against diphtheria will be practised in schools just as regularly as vaccination is against small-pox. Unfortunately, the duration of the period of immunity obtained by anti-diphtheritic inoculation is far from being as long as that obtained by vaccination. At the Trousseau Hospital M. Netter inoculated 502 children belonging to 200 families with anti-diphtheritic serum. From every family a previous case of diphtheria had been sent to hospital. The average dose of serum was 10 cubic centimetres, and not only did it not give rise to unpleasant sequelæ but it appeared to be remarkably efficacious. Only 13 children were attacked by diphtheria, seven within 24 hours and six after one month. No case occurred between the second and the twenty-eighth day. Bacteriological examinations were made of the throats of 476 children and Löffler's bacillus was found in 150 instances. The utility of these preventive injections is strikingly shown by a comparison with the cases of 491 children not immunised coming from families a member of which had also been sent to hospital with diphtheria. Among these 86 cases occurred, as against 13 in the inoculated. None of the 13 cases was fatal or even severe, while among the 86 cases 18 were fatal and 39 severe. This method, therefore, would appear to give efficacious protection against the spread of diphtheria in families.

### *The Separation of Radica and Doodica.*

The xiphopagous "phenomenon" which has been exhibited this winter in Paris at Barnum's Show under the names of "Radica and Doodica" was surgically divided on Feb. 9th in Dr. Doyen's clinic. The health of the two children has been in an unsatisfactory state for some time past and owing to climatic conditions to which they were not adapted they have lost flesh. Radica, indeed, is obviously suffering from tuberculous peritonitis. Mrs. Coolman, who looked after the children, took them to the Trousseau Hospital, where they were tended with great care in order to get them into a proper state of health for the operation of separation. Professor Kirmisson, who has recently been elected to the chair of infantile surgery, had been chosen to perform the operation by Dr. Guinon, under whose care the children were. All of a sudden, however, Mrs. Coolman took the children out of the hospital and transferred them to Dr. Doyen's clinic. This course of action gave rise to many attacks upon Dr. Doyen in the political journals which are friendly to Professor Kirmisson. It must be remembered, however, that Mrs. Coolman had every right to choose the surgeon whom she preferred and that there is no proof that undue influence was brought to bear upon her by the friends of Dr. Doyen. Certainly, the operation is a grand advertisement for Dr. Doyen, for the daily press has made much of it and Dr. Doyen has not refused to be interviewed. Kinematograph films of the operation were taken. It lasted scarcely 20 minutes and was completely successful. The fleshy band uniting the two sisters was 10 centimetres wide by four centimetres thick. Beneath the skin was some cartilage. The peritoneum lined the interior of the band, which also contained, as was expected, some liver tissue. Vascular communication between the two children had been previously ascertained by giving some methylene blue to one of them which appeared in 10 minutes' time in the urine of the other, when it was drawn off by a catheter. In all similar operations previously performed on this class of monster the difficulty has been to arrest the hæmorrhage from the divided liver tissue. In the present instance, however, this difficulty was effectually met by the application of Dr. Doyen's angiotribe, by which the tissues were compressed until they were no thicker than a sheet of paper and were completely bloodless. They were then ligatured with two catgut ligatures. The peritoneal cavity of Radica, which was tuberculous, was freely washed out and a drain was left in the abdominal wound. The same course was followed in the case of Doodica. The immediate results of the operation were excellent, although the general health of the patients gives rise to fear for the future. However, at the moment of writing, the latest news, which I have personally obtained from Dr. Doyen's clinic, is very good.

Feb. 11th.

## Obituary.

### EDMUND GWYNN, M.D. ST. AND., M.R.C.S. ENG.

WE have to record with deep regret, which is shared by all who knew him, the very sudden death, at the age of 61 years, of Dr. Edmund Gwynn, late medical officer of health of Hampstead. The sad event occurred during a holiday trip in Egypt on Jan. 27th last while travelling up the Nile on a steamer. The cause of death was syncope, and although it now appears that he had premonitions of cardiac weakness he had not mentioned the matter to his family, upon whom the blow fell quite unexpectedly. Dr. Gwynn held the office of medical officer of health of the parish, and latterly of the Borough, of Hampstead for a period of 22 years, resigning his position only last year. During part of his tenure of the post of medical officer of health he also practised in Hampstead, retiring from practice in 1895, and thus for the last six years he was able to give his undivided attention to matters connected with public health.

Dr. Gwynn's work as medical officer of health was appreciated beyond his own borough, his reports were lucid and suggestive, and he was justly proud of the sanitary progress of his district during his term of office as shown by the decline in the death-rate which compared most favourably with that of other communities. He was especially active in suppressing the outbreak of small-pox which visited Hampstead about 18 years ago. His reputation as a health officer was recognised by his election as president of the Society of Medical Officers of Health, in which capacity he justified in every way the good opinion of his colleagues, proving an excellent president. He gave

(FROM OUR OWN CORRESPONDENTS.)

### *Death of Dr. Robert Peel Ritchie of Edinburgh.*

BY the death of Dr. R. P. Ritchie on Feb. 10th Edinburgh has lost another of her prominent practitioners. Dr. Ritchie received his medical education in Edinburgh and became a graduate of the University of Edinburgh in 1856. In his early years he had some experience of asylum practice at Bethnall House Asylum, London, but he soon returned to his native city where he spent the rest of his professional life. He was a Fellow of the Royal College of Physicians of Edinburgh and was for a number of years the honorary treasurer of the College, in which capacity he displayed distinct financial ability. At a later date he occupied the post of President for two years, in which position he never failed to uphold the dignity and the interests of his College and of his profession. He thereafter held the post of Vice-President of the College with a seat on the council, and he was ever assiduous in his attention to all matters which came before that body. He held the office of physician to the Royal Hospital for Sick Children, and after his term of office in that capacity had expired he was elected a consulting physician to that institution, a position which he occupied until his death. Dr. Ritchie was a Conservative and an adherent to the Established Church and he was warmly interested in civic affairs. Although he was never a member of the town council he took a keen interest in supporting the candidate for his own ward whom he thought best qualified to do the work of the city. He was a member of the parish council and took a prominent part in the deliberations of that body. Dr. Ritchie did not contribute to any extent to the literature of his profession, but his name will ever be associated with the History of his own College which he published some years ago and which included a history of early medical practice and medical teaching in Edinburgh. On the ethical and moral side he was always an upright, straightforward, and honourable gentleman, with no tendency to devious courses or underground workings. Dr. Ritchie's wife died some years ago, but he is survived by two sons, one of whom is in the navy and the other is a member of the medical profession; he is at present one of the resident physicians in the Edinburgh Royal Infirmary.

### *Nurses' Entertainment in Edinburgh.*

On the evening of Feb 10th the Lord Provost and magistrates of Edinburgh gave a reception, followed by a dance, to the nurses of the City Hospital. Invitations had also been issued to nurses of the Royal Infirmary, of the Royal Hospital for Sick Children, and of other institutions in Edinburgh and its vicinity, some invitations being extended even to Glasgow. The entertainment was held in the Music Hall and Assembly Rooms. Fully 400 nurses were present, as well as a large number of other guests. In the absence of the Lord Provost Bailie Brown welcomed the nurses and explained that a similar entertainment had been planned for last year, but could not be held owing to Queen Victoria's death.

### *Victoria Hospital for Consumption, Edinburgh*

A considerable enlargement of the Victoria Hospital for Consumption, Craigleith, has been arranged and will probably be carried through in the course of the present year. Mr. William Younger, M.P., has intimated his intention of subscribing a sufficient sum to build an annexe to the hospital capable of accommodating eight patients, and the committee of management contemplates the erection of two additional annexes, each capable of accommodating 12 patients The total accommodation will thus be doubled and the hospital will be enabled to undertake a proportionately larger amount of the incalculably useful work which it is doing at present.

### *Aberdeen Royal Infirmary.*

The report of the Aberdeen Royal Infirmary for the past year shows that the total income was £11,224 and that the expenditure was £10,968. On most of the items of income a decrease is shown. The small sum charged against interest explains the saving in the amount expended. Lord Mount Stephen's generous gift of £25,000 removed the debt which had weighed so heavily on the institution since its enlargement. The average daily number of patients was 205·2. The annual cost per occupied bed was £49 13*s.* 2*d.*—a decrease of £1 0*s.* 7*d.* Four beds have been endowed during the past year. The only change in the medical staff to be recorded is the resignation of Mr. John Cromar, one of the dental surgeons, and the appointment of Dr. J. Crombie to the sole charge of the dental department. A special department for the study of diseases of the skin has been formed and is under the guidance of Dr. John F. Christie. Mr. John B. Findlay has been appointed clerk and treasurer.

### *Aberdeen Convalescent Hospital.*

The annual report of the Aberdeen Convalescent Hospital shows that the income was £497 and the expenditure £553, leaving a deficiency of £56, attributable to a falling away in the amount of legacies received. The average daily number of patients resident was 14·7, as against 15·8 in 1900. The average stay of each patient was 21·4 days.

### *Aberdeen Royal Lunatic Asylum.*

The report of the Aberdeen Royal Lunatic Asylum has been issued. It shows that the number of patients continues to increase, there being 929 at the close of 1901, as against 887 in 1900. The income for the year was £33,640, and the expenditure was £30,939, leaving a balance of £2701. The surplus was disposed of as follows:—£2000 to meet depreciation and £701 towards the cost of the reconstruction scheme The directors are of opinion that the reconstruction of the main asylum should not yet be undertaken.

# IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Small-pox in Dublin*

A CASE of small-pox was discovered in Dublin on Feb. 10th, the patient being a young man who had come from Glasgow in search of work. Feeling ill he called at the dispensary in Grand Canal-street. The medical officer there diagnosed small-pox and communicated with the public health authorities who had the patient removed at once to Cork-street Fever Hospital. The chairman of the Public Health Committee of the Corporation (Sir Thomas Pile) on being informed of the matter wrote to the hospital suggesting that the patient should be removed to the convalescent home at Finglas. The inmates of that suburban and isolated institution were at once cleared out and the case of small-pox was placed under treatment there. At the last meeting of the Public Health Committee, which was held on Jan 23rd, a report was presented in reference to the possible appearance of small-pox in Dublin and the hospital accommodation available. It appeared that the Pigeon House site could not be utilised on account of the extensive operations of the corporation in connexion with the new electrical installation for the lighting of the city. It was decided, therefore, that the board of Cork-street Fever Hospital should be approached on the subject; although that seemed a doubtful project. inasmuch as it was well known that on the last occasion when during an epidemic small-pox patients were received there the inhabitants of that crowded neighbourhood suffered more severely from the disease than did those of any other area of Dublin. Some alarm is felt in Dublin, for it is natural to suppose that some of the other 25 lodgers in the crowded house in Townsend-street whence the patient came may by this time have contracted the infection; in fact, the evening papers of Feb. 11th state that one other doubtful case from that place has already been removed to the Finglas establishment.

### *Ulster Medical Society.*

At the meeting of the Ulster Medical Society, held in the Belfast Museum on Feb. 6th, the President, Professor W. Whitla, showed a case of Enlargement of the Spleen, and Dr. W. B. McQuitty showed a case of Aortic Stenosis. Dr J. S. Darling (Lurgan) read a paper on "Epidemic Diarrhœa," and Dr R J. Johnstone described the bacteriology of some of the cases, and Dr. John Campbell read a paper on "Some Forms of Puerperal Sepsis." Interesting discussions followed the reading of these papers.

### *The Royal University of Ireland.*

At a meeting of the Senate, held in Dublin on Feb. 7th, the following examiners were appointed for the year 1902:

**Freemasonry.**—*The Rahere Lodge, No. 2546.*—An ordinary meeting of this Lodge was held at Frascati's Restaurant, W., on Feb. 11th, Bro. P. S. Abraham, M.D., W.M., in the chair. Bro. Walton R. Read was admitted to the third degree. Bros. Harke, Yetts, and Dunn were admitted to the second degree and W. Bro. F. T. Vaisey was elected a joining member. Most of the Worshipful Masters of the other medical lodges in London attended the meeting as honorary members of the Rahere Lodge. A sum of two guineas was voted from the Lodge funds to the Soldiers' and Sailors' Families Association.

**University College (Bristol) Colston Society.**—The annual dinner of this society was held on Feb. 5th at University College, Bristol, under the presidency of Mr. P. J. Worsley, in the absence through illness of Sir F. Wills. Amongst the company were the Bishop of Bristol, the Bishop of Hereford, the Lord Mayor of Bristol, and Mr. R. B. Haldane, K.C., M.P During the evening £400 were collected for the society, and it was announced that two munificent offers had been made by Sir W. H. Wills and Sir F. Wills of £1000 each to University College, Bristol, conditional on three other equal amounts being forthcoming.

**A Long Hospital Record.**—It is seldom that so long a period of 75 years of service on a hospital staff can be recorded in one family. On Jan. 29th, 1902, Mr. Andrew Boutflower completed 31 years' service as honorary surgeon to the Salford Royal Hospital, immediately following a period of 44 years' service performed in the same capacity by his father, the late Mr. John Boutflower. As a memento of this occasion Mr. Boutflower's colleagues at the Salford Royal Hospital presented him on Jan. 29th with an early English silver salver engraved with the family crest and suitably inscribed.

**Chinese Medical Missions.**—At the Torquay Museum, on Feb 5th, Mr. A. T. Kember, F.R.C.S. Edin., of the Church Missionary Society, gave an interesting lecture on medical work in China. Mr. Kember is attached to the Hangchow Hospital, which contains 200 beds and admits about 1000 in-patients annually, 30,000 out-patients being treated in the 12 months. He alluded to the opium habit in China, and said that in some districts 80 per cent. of the men were opium-smokers and 20 per cent. were "opium-sots," while 20 per cent. of the women were also addicted to the habit.

**University of Cambridge.**—Professor Bradbury, Dr D. MacAlister, Professor Woodhead, and Professor S. Delépine of Manchester have been appointed examiners in pharmacology and general pathology for the examination in June, 1902 Schedules for the examination have been issued by the Medical Board.—Professor J. Reynolds Green, Sc.D., F.R.S., has been elected to a Fellowship at Downing College.—Dr. D. MacAlister has been appointed an elector to the Downing Professorship of Medicine; Dr. A. Hill an elector to the Professorship of Anatomy; Professor McKendrick an elector to the Professorship of Physiology; Professor Chiene an elector to the Professorship of Surgery; and Lord Lister an elector to the Professorship of Pathology.

**The Royal Institution.**—An animal recently discovered in Central Africa, and known as the okapi, formed the subject of the Friday evening discourse delivered at the Royal Institution by Professor Ray Lankester on Feb. 7th A stuffed specimen is on view in a glass case in the Natural History Museum at South Kensington. It has been described as a giraffe-like animal, but as regards external conformation the resemblance is by no means close. The body and neck of the specimen are quite free from mottling of any kind and are of a pleasing extremely dark-brown colour. The fore-legs and the hind-legs are nearly of the same length The fore-legs, the hind-legs, and the haunches are marked with horizontal stripes like those of a zebra. In height it seems to be about four feet nine inches, measured over the wither or highest part of the spine above the shoulder; it is therefore of about the same height as a horse of between 14 and 15 hands. It has somewhat large ears, bifid hoofs, and no horns; its neck is like that of a horse much more than that of a giraffe; its coat is smooth, short, and bright. The specimen would easily stand under the belly of a large giraffe which is beside it Professor Lankester said that Sir Harry Johnston found portions of its skin in the possession of dwarfs who inhabited the Semliki forest to the west of Victoria Lake and who eventually obtained for him a skin and two skulls. The skull showed a swelling above the eye, where it was probable that the horn would grow if there was one, but this was not the place where the horn grew in the antelope and giraffe. Evidence of the affinity of the okapi and the giraffe was to be found in the fact that they were the only known animals in which the canine teeth in the lower jaw were bifoliate. The helladotherium, remains of which had been found in Greece, was probably related to the okapi.

**Presentation.**—Mr. Rutherford Harris of Newport (Mon.) was on Feb. 3rd presented by the Conservatives of the Monmouth boroughs with a silver service, weighing 2000 ounces, and an address testifying to the friendship and esteem of his supporters at the last election in Newport, Monmouth, and Usk. The presentation was made by Lord Tredegar.

**Literary Intelligence.**—Messrs. D. C. Heath and Co. have in the press for early issue a book entitled "Introduction to the Study of the Dependent, Defective, and Delinquent Classes and of their Social Treatment." The author is Dr. Henderson, Professor of Sociology at Chicago University.—Messrs. P. S. King and Son, of Orchard House, Westminster, have in the press for publication early in March a practical guide for the use of the inspector of nuisances by Mr. H. Lemmoin-Cannon.

**The late Dr. T. Lewis.**—Dr. Thomas Lewis, consulting physician to the Carmarthenshire Infirmary, died at his residence in Spilman-street, Carmarthen, on Feb. 7th, in his eighty-eighth year. He took the diploma of M.R.C.S. Eng. in 1838 and graduated at London University as M.B. in 1839 and as M.D. in 1859. The deceased had long practised in Carmarthen, where he was much respected, but he had retired from professional work some years ago. Dr. Lewis leaves a widow and six children, two of his sons being members of the medical profession.

**Clifton Dispensary.**—The eighty-ninth annual meeting of the subscribers to the Clifton Dispensary was held on Feb. 4th, under the presidency of the Rev. R. W. Southby. The medical report stated that 3465 patients (including 73 midwifery cases) had been treated during 1901, a against 3668 in 1900. The financial statement showed that the income amounted to £637 and a favourable balance of £196 remained at the end of the year. The chairman alluded in terms of regret to the resignation of Dr. J. G. Swayne, the honorary consulting accoucheur, who had been for upwards of 40 years connected with the institution.

**"Knowledge" and Microscopical Work.**—The editor of *Knowledge*, with the object of making the microscopical section of his journal more extensively serviceable to microscopists, has commenced with the January issue a series of notes dealing with the collection, preparation, and mounting of various objects, and in order to render these thoroughly practical material will from time to time be offered to readers to enable them to follow the instructions given. The first notes dealt with foraminifera and cleaned and uncleaned material is now ready.

**Gifts to Hospitals.**—The Liverpool Hospital for Cancer and Diseases of the Skin has received from Sir Thomas Brocklebank a donation of £1000. This sum, it is felt, will justify the board in carrying out some improvements long considered to be necessary.—At a recent meeting of the management committee of the General Hospital, Birmingham, a letter was read from Sir John C. Holder, Bart., expressing his satisfaction that the committee had determined to erect a laundry for the hospital upon land at Erdington, near the Jaffray Suburban Hospital. He believed it would be a great saving to the institution, and he should have great pleasure, subject to the estimates meeting with his approval, in himself defraying the cost of the building and its equipment.

**The After Care Association** held its annual meeting at Lambeth Palace on Feb. 8th, when the Archbishop of Canterbury presided. The chief objects of this association are to facilitate the re-admission of poor persons discharged recovered from lunatic asylums into social life—(1) by obtaining for them when needful an interval of change of scene and air often so beneficial on recovery from ordinary sickness; (2) by giving them grants of money and clothing; and (3) by assisting them to obtain suitable employment.

a notable presidential address and showed a decided literary bent, and at the close of his term of office as president he was elected vice president and treasurer of this society It was while president of the Society of Medical Officers of Health that he read a valuable paper on Shakespeare and Sanitation at the Stratford on-Avon meeting, another contribution, also on a public health question, was the Jerry Builder in Relation to the Dwellings of the Poor Dr Gwynn was also unanimously elected president of the Hampstead Medical Society two years ago and was president at the time of his death, and in that office he displayed not only intelligent interest in the proceedings but much courtesy and kindly consideration towards the members of the society It is pleasant to record that his medical colleagues in Hampstead showed their appreciation of the good relations which had existed for so long between their medical officer of health and themselves by presenting him in July last with some plate and an illuminated address expressing their goodwill and esteem and we have reason to believe that this presentation and the kind words accompanying it were greatly valued by him Dr Gwynn leaves a widow and daughters to mourn their loss and they have the sympathy of the whole community

He had two sons and here is a sad episode in his life They both died while on the threshold of manhood and full of promise about six or seven years ago and within a year of each other One of them was destined for the medical profession Such a double misfortune might well arrest the energies of a strong man, but the subject of this notice, grieving always but never repining, continued to toil on till his work was accomplished

### WALTER WYKESMITH, L R C P EDIN, L M, M R C S ENG, F R C S EDIN

MR. W WYKESMITH, who died on Feb 3rd at Poole, in Dorsetshire, received his medical education at King's College, London, and also in Paris For many years he was in practice at Wimborne but his health failing he retired from active medical work last year and went to reside at Poole To him Wimborne is mainly indebted for its efficient water supply, the Wimborne Water Company owing its inception to Mr Wykesmith's interest and energy He was a member of the governing body of Wimborne Minster and was a staunch Churchman He also took a very active interest in Freemasonry He joined the St Cuthberga Lodge in 1873 and received provincial rank as assistant director of ceremonies in 1881 He also received the rank of provincial junior warden in the Mark degree Mr Wykesmith, who was approaching his sixtieth year, leaves a daughter and three sons to mourn their loss His wife died in December last

### WILLIAM MARTINDALE, F C S, F L S

PHARMACY has sustained a great loss in the death of Mr William Martindale which took place suddenly at his town residence on Feb 2nd He was well known to most medical men as an authority on pharmaceutical affairs, he being joint author with Dr W Wynn Westcott of the invaluable little book known as 'The Extra Pharmacopœia' How far this book has been appreciated may be gathered from the fact that since the first issue in 1883 no less than 10 editions have been published The first edition was sold out within a fortnight of its issue and the second edition, thoroughly revised, appeared within a few months of the issue of the first edition Mr Martindale devoted a good deal of his time to the improvement of pharmaceutical preparations He knew the difficulties of pharmaceutical study in all its branches Indeed his practical knowledge not only of pharmacy but of the relationship of pharmacy to medicine and to the qualifications of pharmacists and of the laws of the country governing their conduct made him an excellent president of the Pharmaceutical Society. He also had occupied the position of president of the British Pharmaceutical Conference Quite recently he had been devoting much time and study to the important legislative questions now being considered by the Poisons Committee of the Privy Council It is to be regretted that this committee has no longer the advantage of the admittedly valuable services of Mr William Martindale who served upon it as the direct representative of the pharmaceutical profession

*Second Division* —Lacey Bathurst, St Thomas's Hospital, Leonard Hubert Henry Boys Middlesex Hospital, Charles Noel Davis, St Bartholomew's Hospital, William James Edgar, St Thomas's Hospital, Harry Farncombe University College, Florence Erin Gubb London (Royal Free Hospital) School of Medicine for Women Eric Crichton Hood Yorkshire College Henry Arthur Kellond Knight St Bartholomew's Hospital John Tryweryn Lloyd and Daniel Joseph Mulholland University College Liverpool, Evan Williams Parry St Thomas's Hospital John Mackay Plews, St Bartholomew's Hospital, Thomas Phare Puddicombe St Thomas's Hospital Samuel Henry Sweet, University College, Cardiff, Barbara Tchaykovsky, B Sc London (Royal Free Hospital) School of Medicine for Women and Bedford College, Louis Leopold Arthur W Thomson St Mary's Hospital, and Francis Henry Whitehead St Thomas's Hospital

N B —The foregoing list published for the convenience of candidates, is provisional only and is not final until the reports of the examiners shall have been confirmed by the Senate

ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS IN IRELAND —The following candidates have passed the examination for the Conjoint Diploma in Public Health —

Thomas Hennessy F R C S Irel John O Donoghue F R C S Irel, and D M Saunders Major, R A M C

UNFOUNDED CHARGE AGAINST A WORKHOUSE MEDICAL OFFICER —At a recent meeting of a committee of the Liverpool Board of Guardians one of the members stated that a middle aged pedlar, named Richard Williams, had made a complaint to the effect that when he applied for medical advice at the workhouse surgery the medical officer without saying anything threw him on the floor, forcibly administered chloroform, and slapped him several times on the face, when he recovered consciousness The medical officer's report, which was then submitted, stated that Williams was a well-known malingerer whose practice was to drop to the ground at the workhouse gates and to be carried into the house apparently exhausted and dying On the day of the incidents complained of he gained admission by the usual tactics When seen by the medical officer he was trembling violently and was apparently in a state of collapse The ordinary treatment for malingering was then adopted—namely, ammonia on a chloroform mask applied to the face, and a few minutes later he walked out of the workhouse Williams had been subjected to the same treatment only three weeks previously, and on this occasion also he quickly walked out perfectly well The committee was unanimously of opinion that the man had no ground of complaint.

Human Body in the Dissecting-room. By Edmund M. Holmes, A.B., M.D. Second Edition. Price not stated.

PENTLAND, YOUNG J., Edinburgh and London.

The Fish River Bush, South Africa, and its Wild Animals. By W. T. Black, M.R.C.S., L.S.A., Assistant Surgeon, Army Medical Staff. Price not stated.

Transactions of the Epidemiological Society of London. New Series. Vol. xx. Session 1900-1901. Price not stated.

SIMPKIN, MARSHALL, HAMILTON, KENT, AND CO., LIMITED, London.

Where to Buy: a Guide to the Professions and Business Houses. By C. M. Knowles. Price 3s. 6d.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ALLAN, G., M.D. Aberd., has been appointed Clinical Assistant to the Medical Department of Prince Alfred Hospital, Sydney.

ANDERSON, D. LECHMERE, L.R.C.P., L.R.C.S. Edin., Medical Officer of Health for Peterhead and Ellon, Scotland, has been appointed Medical Officer of Health for the Borough of Doncaster and the Urban Districts of Balby-with-Hexthorpe and Wheatley.

AWDRY, WALTER ROBERT, M.B. Durh., M.R.C.S., has been appointed Honorary Medical Officer to the Berkeley Cottage Hospital.

BATTEN, RAYNER WINTERBOTHAM, M.D. Lond., F.R.C.P., M.R.C.S., has been appointed Honorary Consulting Physician to the Berkeley Cottage Hospital.

BRUNYATE, T. T., M.A., M.D. Oxon., has been appointed Physician to St. Bartholomew's Hospital, Rochester.

DEANE, EDWARD WILKINSON, M.B. Melb., has been appointed Public Vaccinator for the North-western District, Melbourne, Victoria.

FETHERSTON, RICHARD HERBERT, M.D. Melb., has been appointed Public Vaccinator for the Metropolitan District, Melbourne, Victoria.

FULLERTON, ROBERT JOHN, L.R.C.P. Edin., has been appointed Public Vaccinator for the Northern District, Melbourne, Victoria.

HALLIDAY, J. C., M.B., Ch.M. Syd., has been appointed Clinical Assistant to the Ophthalmic Department of Prince Alfred Hospital, Sydney.

HARKNESS, EDWARD, L.R.C.P. Edin., has been appointed Public Vaccinator for the South-eastern District, Melbourne, Victoria.

JACOBS, J. M. C., L D.S Eng., has been appointed Honorary Dental Surgeon to Queen Adelaide's Dispensary, Pollard-row, Bethnal Green.

KATER, N. W., M B. Syd., has been appointed Clinical Assistant to the Medical Department of Prince Alfred Hospital, Sydney.

MUNRO, A. W., M D. Edin., has been appointed Clinical Assistant to the Gynæcological Department of Prince Alfred Hospital, Sydney.

NOLAN, H. R., M.B., Ch.M. Syd., has been appointed Clinical Assistant to the Throat, Ear, and Nose Department of Prince Alfred Hospital, Sydney.

ORMOND, JAMES SERVICE, M.D. Glasg., has been appointed Medical Officer of Health for the town of Malvern, Victoria.

PADWICK, J. C. M.R.C S., L.R.C P., has been appointed Medical Officer of Health of Bridgnorth Rural District.

PITCAIRN, G. K., M.B., M.S. Edin., has been re-appointed Medical Officer for Littleborough.

POWELL, W. WYNDHAM, F.R.C.S., has been appointed Surgeon to the Westminster General Dispensary.

SHAW, JOHN EDWARD, M.B., C.M. Edin., has been appointed Honorary Physician to the Clifton (Bristol) Dispensary, vice Dr. Fyffe, deceased.

SPENCE, BASIL A., M.B., Ch.B. Edin., has been appointed Dispensary Surgeon to the Bradford Royal Infirmary.

STEVENS, W. MITCHELL, M.D. Lond., L R.C.P. Lond., M.R.C.S., has been appointed Honorary Assistant Physician to the Cardiff Infirmary, vice Dr. Herbert R. Vachell.

TERRY, HEDLEY, M.B., M.Ch. Syd., has been appointed to be Medical Officer to the Aborigines at Kiama, N.S.W.

TURPIN, D. W. M., L.K.Q.C.P., L.R.C.S. Irel., has been appointed District Medical Officer of Shardlow Union.

VACHELL, HERBERT REDWOOD, M.D., C.M. Aberd., M.R.C.S., L.S.A., has been appointed Honorary Physician to the Cardiff Infirmary, vice C. Tanfield Vachell, resigned.

WEARNE, WALTER, M.R.C.S., L S.A., has been re-elected Medical Officer to the Helston (Cornwall) Public Dispensary.

WHEATLEY, JAMES, M.D. Lond., has been appointed Medical Officer of Health to the Shropshire County Council, vice Dr. Porter.

WILLS, ERNEST, M.D. Lond., M.R.C.P., has been appointed County Health Officer and Examiner in Lunacy for Weld County, Colorado, U.S.A.

YOUNG, H. O T., M.D. Glasg., has been appointed Clinical Assistant to the Gynæcological Department of Prince Alfred Hospital, Sydney.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

ASHTON-UNDER-LYNE DISTRICT INFIRMARY.—House Surgeon. Salary £120 a year and board and lodging.

BELGRAVE HOSPITAL FOR CHILDREN.—Ophthalmic Surgeon; Assistant Physician; Assistant Surgeon; Sanitary Officer.

BIRKENHEAD BOROUGH HOSPITAL.—Junior Male House Surgeon. Salary £80 per annum, with board and washing.

BLACKBURN COUNTY BOROUGH.—Medical Officer of Health. Salary £550 per annum.

BOOTLE BOROUGH HOSPITAL, Liverpool.—Senior Resident. Salary £100 per annum, with board and laundry.

BRADFORD EYE AND EAR HOSPITAL.—Honorary Surgeon.

BRENTFORD UNION INFIRMARY, WORKHOUSE, AND SCHOOLS.—Assistant Medical Superintendent, unmarried. Salary £100 per annum, with apartments, rations, washing, &c.

BRIDGWATER INFIRMARY.—House Surgeon. Salary £80 a year, with board and residence.

BURY INFIRMARY.—Junior House Surgeon. Salary £90, with residence, board, and attendance.

TOTTENHAM URBAN DISTRICT COUNCIL.—Medical Officer of Health. Salary £500 per annum.

WARNEFORD HOSPITAL, Leamington.—House Surgeon. Salary £100 per annum, with board, washing, and apartments.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

## Births, Marriages, and Deaths.

### BIRTHS.

FISHER.—On Feb. 10th, at Sittingbourne, Kent, the wife of H. Holdrich Fisher, M.D. Lond., of a son.

FREDERICK.—On Feb. 4th, at North Woolwich-road, Silvertown, the wife of Edward G. Frederick, M.R.C.S., L.R.C.P. Lond., of a son.

FRERE.—On Feb. 6th, the wife of A. Hanbury Frere, M.B., C.M., of Diss, Norfolk, of a son.

LOTZ.—On Feb. 3rd, at Fremantle, Western Australia, the wife of H. J. Lotz, L.R.C.P. Lond., M.R.C.S., D.P.H., of a son.

RANDALL.—On Feb. 6th, at Queen's-road, Wimbledon, the wife of Surgeon Philip N. Randall, M.B. Lond, Royal Navy, of a daughter.

### MARRIAGES.

ASH—BRATT.—On Feb. 11th, at Christ Church, Mayfair, London, Lieutenant Colonel Robert Vacy Ash, A.M.S., retired, of Fleetwood, Lancashire, to Florence May, daughter of Henry Bratt, J.P.

WADE—DAWES.—On Feb. 6th, at the parish church of St. Mary, Rye, Sussex, Ernest Wentworth Wade, of Harleston, Norfolk, M.D. Dubl., to Elsie Katherine, eldest daughter of Walter Dawes, solicitor, Rye.

WARING—MILVAIN.—On Feb. 10th, at Adwick-le-Street, near Doncaster, Alfred John Waring, M.B. Lond., to Isabel Catherine Milvain, daughter of the late James Milvain, Newcastle-on-Tyne.

### DEATHS.

BLATHERWICK.—On Feb. 6th, at his residence, Queen's Mead-road, Bromley, Kent, Deputy-Surgeon-General Thomas Blatherwick, in his 79th year.

FORT.—On Feb. 10th, at Standerton, of enteric fever, Percy Reginald Fort, L.R.C.P. Lond., aged 28 years.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

This association undoubtedly does very useful work, but, like many other charities, is sadly crippled in its work from want of funds It was stated at the meeting that the number of patients discharged from all the lunatic asylums of the country was about 7000 a year, and of this number but very few were provided for by their friends

PLYMOUTH DENTAL HOSPITAL The annual meeting of the subscribers of this institution was held on Feb 5th, under the presidency of Mr J Elliot Square, F R C S Eng The report stated that 1990 patients had been treated during 1901 The financial statement showed a favourable balance of £4

OPPOSITION TO THE "CONSCIENTIOUS OBJECTION" CLAUSE —At the meeting of the Bodmin Town Council held on Feb 4th, and also at the meeting of the Exmouth District Council held on Feb 5th, it was decided to support a petition for the repeal of the clause in the Vaccination Act of 1898 relative to conscientious objections to vaccination

DR G VIVIAN POORE will occupy the chair on the occasion of the complimentary dinner to be given to Captain E T Inkson, V C , R A M C , by the Union Society of University College and Hospital on Friday, Feb 21st, at the Café Royal, Regent street, W Tickets (6*s* 6*d* each) can be obtained on application to Mr W L Scott, University College, Gower street W C

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS

### *The Registration of Plumbers*

THE Bill for the establishment of a national system for the registration of plumbers has been introduced once more this time in the House of Lords Lord Glenesk has charge of the Bill and at a recent sitting of the House of Lords he obtained a second reading for it

### *Medical Acts (Extension) Bill*

Attached to the Medical Acts (Extension) Bill introduced by General Laurie is a memorandum in the following terms—viz 'Since the passing of the Medical Act 1858 very great advance has been made in medical education throughout the empire and especially in the self governing colonies This Bill provides that where the examiners and course of education at the principal colonial schools of medicine are in all respects the same as those practised in the United Kingdom and subject to the supervision of the General Medical Council medical men from Greater Britain should when proved to be properly qualified be admissible to serve the Empire in the naval and military and civil services of the Crown Surgeons of the highest standing in Canada and holding commissions from His Majesty in the militia volunteered for service in South Africa and a complete field hospital was offered by Canada and in both cases the War Office refused to accept such service on the ground that it was contrary to the Medical Act of 1858 to permit a colonially trained surgeon to attend professionally to British troops The object of the amending *Bill* is to remove this disqualification The second reading of the Bill was put down for Wednesday, Feb 12th but other business occupied the House on that day and it had to be postponed

## HOUSE OF COMMONS

### FRIDAY FEB 7TH

### *Inoculation against Enteric Fever*

Mr EUGENE WASON asked the Secretary of State for War whether he could now give any information as to the result of inoculation against enteric fever amongst the troops in South Africa, and what proportion of those who had died from enteric fever were inoculated, and how many were not inoculated —Lord STANLEY replied: The report of a civil surgeon who was specially detailed to collect the information in South Africa has not yet been completed I am not, therefore, in a position to give the information desired

### MONDAY FEB 10TH

### *The Housing of the Working-classes*

Mr LONG in reply to a question with regard to the housing of the working-classes said that he could not at present state when he should be in a position to move for the appointment of the proposed Select Committee to inquire into the period for the repayment of loans raised by local authorities but due notice would be given of the motion He did not propose that the committee should be asked to inquire into other matters in connexion with the housing of the working-classes

### *Suspected Beer Poisoning at Halifax*

Sir CUTHBERT QUILTER asked the President of the Local Government Board whether his attention had been called to the recent cases of suspected beer poisoning in the borough of Halifax, whether any investigation by his department or by any local authority had taken place, and if so with what result?—Mr. LONG replied My attention has been called to the cases referred to in the question and I have ascertained that local investigations are now being made by the Assistant Commissioner of the Royal Commission on Arsenical Poisoning as well as by the medical officer of health of the borough

### *Poor law Medical Officers in Ireland*

Mr J P FARRELL asked the Chief Secretary to the Lord Lieutenant of Ireland having regard to the fact that although medical officers summoned by subpœna to give evidence in criminal cases were paid their fees at professional rates in the cases of dispensary officers absent on such duties the ratepayers were called upon to pay a locum tenent, whether he would consider the advisability of ordering in future that such medical officers must provide their own substitute —Mr WYNDHAM replied The Local Government Board has been advised that a medical officer compelled by subpœna to be absent from his district is temporarily incapacitated from performing his duties within the meaning of the Relief Act and Orders and the board of guardians is bound therefore to make provision for the care of the sick poor during his absence by employing and paying a temporary substitute It is a matter of very rare occurrence for a board of guardians to have to incur expenses such as these

### *The Supply of Vaccine Lymph*

Mr BARTLEY asked the President of the Local Government Board whether seeing the importance of all persons being vaccinated and revaccinated with vaccine lymph of guaranteed quality made in this country and not obtained from abroad or from other sources which were not so guaranteed he would take steps to provide with the *least possible delay an adequate supply of Government lymph* so that every qualified medical practitioner should be able to purchase such Government lymph in such quantities as he might require and at a price just sufficient to pay the cost of its production —Mr LONG replied Having regard to the interest felt in all matters connected with small pox at the present time perhaps I may be allowed to make a short statement in answer to this question The duty undertaken by *the Government in 1898 was to provide for primary* vaccination by public vaccinators and this duty, I may say has been completely fulfilled It has also been the desire of the Government as far as possible to provide public vaccinators with lymph for revaccinations and this has been done to the utmost extent practicable In ordinary times it has been found sufficient to issue from 8000 to 10 000 charges of lymph weekly Since however, the epidemic of small pox began this output has been largely increased and the establishment is now producing some 50 000 charges a week I may explain that there are several difficulties in connexion with the manufacture of glycerinated lymph In the first place, it is not possible to store it to any large extent because the period for which it will keep is so uncertain and I may state that when the demand in consequence of the outbreak of small pox began to increase there was in reserve the full amount which it was thought practicable to retain Further, the lymph takes some weeks to mature especially as it is of importance that all practicable means should be used to test its efficiency and purity before it is issued Moreover, there is great fluctuation in the demand owing to the habit of so many persons to defer vaccination until small pox is imminent Thus in a single fortnight recently the applications for lymph from public vaccinators which had previously risen to four times the normal demand suddenly more than doubled, From the inquiries which I have caused to be made I understand that an ample supply of glycerinated calf lymph can be obtained from unofficial sources and that there is no reason to doubt that it is satisfactory in quality It would, I think, be unfortunate at this moment to enter into competition with private enterprise in this matter, *Looking to the* considerations I have mentioned I do not see my way at the present time to accede to the suggestion of my hon friend —Mr BARTLEY asked whether there was any guarantee as to the efficiency of the lymph —Mr LONG: There is no guarantee in connexion with either official or non-official lymph Two years ago there was an independent inquiry conducted by THE LANCET into the lymph generally supplied On that occasion they found considerable fault with the lymph *supplied* by the Local Government Board and placed it fifth in the list of lymphs arranged in the order of merit It is impossible to guarantee lymph What the Local Government Board does is to secure that the utmost care and trouble are taken in its preparation in the hope that it shall prove pure and efficacious The lymph provided by private commercial firms is I believe at the present moment of excellent quality and as good as we can produce *ourselves —Mr* PEASE *asked whether it was* the fact that large quantities of lymph had been received from the French Government —Mr LONG No sir, I am not aware of any lymph being supplied by the French Government but there is a considerable manufacture of lymph by private firms in France which so far as I know is of a thoroughly satisfactory character

### TUESDAY, FEB 11TH

### *Small pox Accommodation at Aldershot.*

Colonel TUFNELL asked the Secretary of State for War whether he would state by whose authority huts had been erected on Thorn Hill Aldershot specially for the reception of small pox cases, the site being within a stone's throw of the abattoir established for the killing of animals for the troops at that station —Mr BRODRICK replied: This service was carried out by *the general officer commanding the First Army* Corps on his own initiative The site is close to the existing isolation hospital It is 200 yards from the present supply depôt and 400 yards from the new abattoir which is nearly finished

Major RASCH May I ask whether this is the same genius who ordered sewage milk to be served out to the troops?—Mr BRODRICK No sewage milk was ever served out to the troops

Sir WALTER FOSTER: *Is it not an understood thing that these huts* should be at a distance of at least 400 yards? Mr BRODRICK: I have no doubt that the medical authorities were consulted as regards the distance but medical authorities do sometimes disagree upon these points

## BOOKS, ETC , RECEIVED

MACMILLAN AND CO Limited, London and New York.

Atlas of Practical Elementary *Zootomy* (Being a Revised Edition of the Zoological Portion of the Atlas of Practical Elementary Biology ) By G B Howes, LL D F R S With a Preface to the First Edition by the late Right Hon Professor T H Huxley, P C F R S Price 10*s* net

NEW ERA PRINTING COMPANY, Lancaster, Pa., U S.A.

Outlines of Anatomy A Guide to the Methodical Study of the dilating it sufficiently so as to allow the escape of the hooked end. This not being successful, seizing the free end and pulling firmly upon it, he cautiously cut round the pin with a pair of scissors, thus easily extricating it, and without any hæmorrhage, either external or internal, the part healing at once without any further trouble and the patient recovering perfectly.

This case is interesting from its exceptional rarity, and as showing what unaided nature can do, especially in these days when, as Sir Felix Semon has pointed out with reference to another region of surgery, there is such a frantic rush to the stern arbitrament of the knife in all sorts of cases.—I am, Sirs, yours faithfully,

B. STRACHAN, M.B. Glasg.

Sunderland, Jan. 29th, 1902.

### SERO-THERAPY AND GOVERNMENT CONTROL.

AT the conclusion of a lecture at the Royal Institution on Feb. 11th Professor A. Macfadyen urged the desirability of a Government laboratory being established in which the preparation and standardisation of sera and antitoxins should be conducted. It has been for some time strongly recognised that a control laboratary is needed, and the Government ought to add a State biological laboratory to its present equipment, which at present only admits of the control of the Excise and the administration of the Food and Drugs Acts at the chemical laboratories in Clement's-inn. At the present time the need of some official control is particularly felt in regard to lymph for vaccination.

### WANTED—A PRIVATE HOSPITAL.

*To the Editors of* THE LANCET.

SIRS,—Could you or one of your readers tell me of a home or private hospital for a young lad who is suffering from diabetes? I find that in his own house the diet cannot be properly restricted and I wish to put him where this can be strictly attended to.

I am, Sirs, yours faithfully,
SACCHARUM.

Feb. 2nd, 1902.

### A CURE FOR WARTS.

*To the Editors of* THE LANCET.

SIRS,—In answer to the query by "At My Wit's End" in THE LANCET of Feb. 8th, p. 420, in reference to the cure of warts, I would suggest that your correspondent revaccinates his patient. I have reported the effects of revaccination upon warts in THE LANCET of Sept. 22nd, 1900, p. 876.

I am, Sirs, yours faithfully,
J. D. STAPLE, M.R.C.S. Eng., L.S.A.

Bristol, Feb. 8th, 1902.

*To the Editors of* THE LANCET.

SIRS,—In answer to "At My Wit's End" I would recommend him to try oleum terebinthinæ applied many (20) times a day and rapidly dried in before a fire. I know of a case where many remedies had been tried (by a specialist), even excision, unsuccessfully and which yielded to the above treatment.

I am, Sirs, yours faithfully,
HEYWOOD SMITH.

Harley-street, Cavendish-square, W., Feb. 10th, 1902.

*To the Editors of* THE LANCET.

SIRS,—Your correspondent "At My Wit's End" asks for a suggestion for treating warts on the hands of a lady. Has he tried making her wear gloves constantly and keeping the inside of the gloves well dusted with a mixture of equal parts of French chalk and calomel carefully mixed? I find it more useful than anything else. Of course, he must look out for symptoms of mercurial absorption, but I have never had any trouble, and generally the warts go.

I am, Sirs, yours faithfully,
SIMPLE SIMON.

Feb. 8th, 1902.

*To the Editors of* THE LANCET.

SIRS,—I am not in the habit of prescribing for one of the *genus homo*, but if the warts that your correspondent complains of in THE LANCET of Feb. 8th, p. 420, belong to the papillomata he will find that a saturated watery solution of sodium hydroxide will remove them. It will first be necessary to get rid of the acetic acid which his patient has been applying to the growths by a liberal application of soap and-water, otherwise the soda solution will be neutralised by the acid. Then with a glass rod apply and smear over each wart one drop of the caustic soda once a day or oftener for two or three days.

I am, Sirs, yours faithfully,
H. M. SINGLETON, M.R.C.V.S.

Ealing, W., Feb. 7th, 1902.

### THE MORTALITY AFTER OPERATIONS FOR APPENDICITIS.

*To the Editors of* THE LANCET.

SIRS,—I should be glad if some of your readers would be kind enough to give their experience regarding cases of appendicitis occurring in their private practice which have been treated by operation during the acute stage. The number of cases within my ken that have died shortly after the operation represent a very large percentage mortality, and the last week two more have been added to the roll. On the other hand, the few cases I have known which for various reasons have refused to submit to operation have in most instances recovered completely. All I ask for is statistics, and if they prove that the risk of death from general peritonitis is less than the risk of death from collapse and other causes after operations (in private houses), then are we general practitioners to continue to recommend the operation?

I am, Sirs, yours faithfully,
M.B.

Jan. 23rd, 1902.

*Nemo.*—We are not sure that we understand our correspondent's letter. Anyhow, no one can be bound by the conditions of a document which he has not seen. He may be bound because he has given his word, and what he has undertaken to do may afterwards be put upon paper; but he is morally bound by his word and not legally bound by the document unless he has seen it and approved it as recording his promise.

*G. S. M.*—"Surgical Emergencies," by W. P. Swain, F.R.C.S. Eng., now in its fifth edition. London: J. and A. Churchill.

*Medical Student.*—The guide in question is now obsolete.

*K. L. S.*—The article is not of sufficient medical interest.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

# Medical Diary for the ensuing Week.

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY (17th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.) St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (2 P.M.).

**THURSDAY (20th).**—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Clinical Cases will be shown by Dr. J. Taylor, Dr. Morison, Dr. Caley, Dr. Eddowes, and others.

# Notes, Short Comments, and Answers to Correspondents.

## CRANIOTOMY IN A LIVING CHILD.

*To the Editors of* THE LANCET.

SIRS,—Is it a fact that there is a definite Papal injunction prohibiting Catholic medical men from sacrificing an unborn infant's life in order to save the mother's life—e.g., when there is hydrocephalus or in a long jammed arm presentation, far advanced, and when the mother is too weak for Cæsarean section? It is a noteworthy fact that in these and analogous cases a medical man is bound to take human life (if a living unborn infant is counted as a life). For if he allows things to take their ordinary course the mother must die By his action he could have saved her life; by his refraining from action he has taken her life in reality; by taking the infant's life he has taken probably (and *probability must be the guide*) a less useful life. But the point is that he is bound to take a life, by action or by refraining from action, and he cannot in doing his duty get out of it, be he Catholic or Protestant.

I am, Sirs, yours faithfully,

Jan. 28th, 1902. INSTES.

⁂ We do not know of any definite Papal injunction to the effect mentioned in our correspondent's letter, but the practice of sacrificing the life of the child to save that of the mother is to the best of our belief not considered lawful by the Roman Catholic Church. The following document is quoted by Capellman, "Medicina Pastoralis," second Latin edition, published at Aix-la-Chapelle in 1891. It is an answer sent by the Holy Office to the Cardinal Archbishop of Lyons.

> "Eminentissime et Reverendissime Domine!
>
> Eminentissimi P.P. mecum Inquisitores Generales in Congregatione Generali habita feria IV, die 28. labentis Maii, ad examen revocarunt dubium ab Eminentia tua propositum: 'An tuto doceri possit in scholis catholicis, licitam esse operationem chirurgicam, quam craniotomiam appellant, quando scilicet ea omissa, mater et filius perituri sint, ea e contra admissa, salvanda sit mater, infante pereunte?' Ac omnibus diu et mature *perpensis, habita quoque ratione eorum, quae hac in re* a peritis catholicis viris conscripta ac ab Eminentia tua huic Congregationi transmissa sunt, respondendum esse duxerunt; *Tuto doceri non posse.* Quam responsionem, cum S. S. D. N. in audientia eiusdem Feriae et Diei plene confirmaverit, Eminentiae tuae communico, tuasque manus humillime deosculor, humillimus ac addictissimus servus verus.
>
> Romae, 21 Mai 1884. R. CARDINALIS MONACO"

—ED. L.

## MEDICAL AID ASSOCIATIONS AND THE GENERAL MEDICAL COUNCIL.

*To the Editors of* THE LANCET.

SIRS,—Among the letters on the above subject no mention has been made of *private* collectors. These men go about canvassing from house to house and are paid either by commission on their collections or by a fixed salary, often with an understanding that if their weekly collections do not increase their salary will be reduced. Now in a small town it soon becomes generally known that the collectors of a certain insurance company have been forbidden to do any canvassing, and, moreover, are not allowed to put on their list any new members whatever. What is the result? Why, the *private* collectors employed by other medical men immediately work upon this to their own advantage. Your correspondent, Mr. John MacCormac, states that medical men are "notoriously unbusinesslike", they would, indeed, be so did they give up an appointment bringing in a good substantial sum a year in order that it might be thrown into the hands of their opponents I would recommend that the 2000 medical men affected by the recent case at Great Yarmouth form a union and demand fair play. The General Medical Council might, with more credit to themselves and a great deal more benefit to general practitioners, turn their attention to the prescribing chemist *On more than one occasion when visiting* patients I have discovered that, instead of taking the medicine they have had from me, they have obtained a bottle from a chemist, still expecting me to go on attending. I have then told them that should the patient die they may as well apply to the chemist for the death certificate.

I am, Sirs, yours faithfully,

Feb. 3rd, 1902. G. P.

## DISINFECTION AND SMALL-POX.

A CORRESPONDENT—a medical man—*writes to us as follows*: "At the present time, when we are again visited by small pox in an epidemic form in the metropolis, it may be considered desirable that a general *disinfection of* the houses, both infected and otherwise, with chlorine in the parishes where the disease is prevalent should be adopted." We cannot think that our correspondent's suggestion is feasible, or that even if it were so it would be useful To disinfect every house in all the parishes where small pox is prevalent would be almost impossible. To disinfect any one house in which a case of infectious disease has occurred is not only possible, but is always done if the matter gets to the ears of the sanitary authorities, and the process, combined with the removal of the patient, goes far to prevent the spread of the infection. But what is the use of disinfecting an uninfected house? As soon as the chlorine was well out of the house there would be nothing to prevent the germs of small pox or any other infectious disease obtaining a footing. The cost, too, of disinfecting a whole parish would be very considerable, and the necessary money would be far better spent in cleansing operations or in improving defective dwellings.

## THE ORDER FOR THE BURIAL OF THE DEAD.

THE honorary secretary of the Funeral Reform Association, whose letter will be found in another column, asks whether all the funeral *service except the committal and the grace might not be said in the* church during inclement weather? There is no reason why it should not, except the very pertinent one that the Book of Common Prayer orders otherwise. There is but little else said at the grave, only the burial antiphon and the antiphon commencing, "I heard a voice ......" together with a versicle and response and two prayers. Until the Prayer-book be revised perhaps the bishop might be able to allow the simple and far more beautiful form of burial service laid down in the first Prayer-book, where the office to be said at the grave was shorter, or else the two collects might in the present office be transferred to the end of the lesson and so said before the coming to the grave.

## WANTED—AN ANNUITY OFFICE.

*To the Editors of* THE LANCET.

SIRS,—Can any of your readers inform me of any office which grants annuities according to the state of health of the applicant after medical examination similar to life insurance? Also if the same is allowed by law for purchase of annuities by trustees?

I am, Sirs, yours faithfully,

Jan. 31st, 1902. M.D.

## "THE FEAR OF SMALL-POX."

THE following letter appeared in the *Newcastle Daily Journal* of Jan. 30th, under the above heading:—

> SIR,—Care should be taken to keep the streets clean. The corporation men should not leave the droppings of the tubs at your back door. There is no need to frighten the people. I have sailed the salt sea Once our mate took the small pox after we got out to sea *I nursed him and he got better without a doctor. No* one else in the ship took the small pox.—I am, etc.,
>
> A SAILOR OF THE QUEEN.

We quite agree with this bold mariner's dictum about keeping the streets clean and fully sympathise with the editor of our contemporary *on account of the corporation* men leaving the *droppings of* the tubs at his back door. But we cannot understand what small pox has to do with it. And, on second thoughts, was it small pox?

## VACCINATION GUARDS.

*To the Editors of* THE LANCET.

SIRS,—I have been asked by several practitioners whether there is a vaccination guard of a similar design to the one which appears illustrated in THE LANCET of Feb. 1st, p 317, but suitable in size for infants and children. May I be allowed to supplement the particulars already given of this appliance by explaining that precisely the same instrument may be used for any age? In the case of infants or children, however, the upper end should be bent over and moulded by the fingers to fit the curve of the shoulder in each case.

I am, Sirs, yours faithfully,

Feb. 9th, 1902. HAYDN BROWN.

## THE STORY OF A HAIRPIN.

*To the Editors of* THE LANCET.

SIRS,—The following case occurred in my experience about 15 years ago. A labourer, tipsy of a Saturday night, was enjoying a fish supper, when, having, as he fancied, swallowed a bone, he asked his housekeeper for a hairpin, which he proceeded forthwith to straighten and convert into a hook for the purpose of fetching it up, thus . In the attempt the hook caught in the fauces and was swallowed. Having been called in, in due course, as there were no urgent symptoms I contented myself with laying him up in bed and putting him on liquids, determined to await events. There was not much discomfort for a week or two, when he had a sharpish attack of bronchitis lasting for another week or two, towards the end of which a hardness was felt in the epigastric region, which by-and-by developed into a distinctly sausage shaped tumour, lying midway between the sternum and the umbilicus, a little to the left of the middle line and sloping obliquely downwards from right to left. This being carefully *palpated from* day to day, a hard point was felt towards the lower end gradually approaching the skin, which it eventually perforated, protruding for about half an inch, and necessitating the use of a tent to prevent contact with the bed-clothes. It could be cautiously drawn out for an inch or two without causing any pain, and I was under the impression at the time that, could he have been constantly watched and kept lying on his back, with a weight attached to it over a pulley in the tent, the thing would gradually have eaten its way through without any *further ado.* But as this was impracticable I secured the assistance of Mr. G. B. Morgan who introduced a tangle tent down through the comparatively open passage alongside the pin with the view of

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1901, which was completed with the issue of Dec. 28th, and the Title-page to the Volume, were given in THE LANCET of Jan 4th.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... .. ... | 0 16 3 | Six Months ... ... ... | 0 17 4 |
| Three Months ... ... | 0 8 2 | Three Months ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

## METEOROLOGICAL READINGS.

*(Taken daily at 8.30 a.m by Steward's Instruments)*

**During the week marked copies of the following newspapers have been received**—*Rivista Medica de San Paulo, Echo, Yorkshire Post, Standard, Bristol Mercury, Liverpool Daily Post, La Caducée, Hong Kong Weekly Press, Herts Advertiser, Times of India, Reading Mercury, Aberdeen Free Press, Mining Journal, Local Government Chronicle, Windsor and Eton Express, Thrapston and Raunds Journal, Review of the River Plate, Revista Ibero-Americana de Ciencias Médicas, Nottingham Guardian, Hertfordshire Mercury, Pharmaceutical Journal, Manchester Guardian, Dublin Evening Telegraph, Southampton Echo, Stafford Advertiser, Glasgow Evening Times, Leeds Mercury, Coventry Herald, Belfast News, Birmingham Daily Mail, Municipal Reformer, Allgemeine Medicinische Central Zeitung, Liverpool Journal of Commerce, Il Policlinico, Halifax Courier, Aberdeen Daily Journal, &c.*

equilibrium, any excess which may occur being subsequently absorbed. This is seen in the *repair* of a wound or a fracture. If, however, the condition is unstable, the cells proliferate continuously without forming the necessary amount of intercellular substance, thus forming a *sarcoma*

Secondly, there is a condition of equilibrium between epithelium and connective tissue with regard to position. If the condition is stable and is disturbed—e.g., by introducing some epithelium into the connective tissue—the epithelial cells may proliferate for a time but are eventually absorbed or encapsulated. If, for example, a few epithelial cells be introduced into the subjacent tissue, as sometimes occurs as a result of trauma, the effect is that the cells proliferate for a time, forming a globular mass of cells or an *implantation pearl*. If a larger portion of epithelium, including the basement membrane, be introduced, the result is an *implantation cyst*. An implantation cyst is the result of the natural tendency of epithelial cells to cover any bare surface. The cells on each side of the included portion proliferate until they line the cavity in which it lies and the cyst subsequently increases in size only by accumulation of its contents. The implantation cyst, therefore, is not a tumour in the strict sense of the word, since the increase in size is not due to an active proliferation of its cells so much as to the retention of its contents. If the original condition between the epithelium and the subjacent tissue is unstable the epithelial cells which are introduced continue to undergo active proliferation and the result is the formation of a *carcinoma*.

In the next place, there is a condition of equilibrium between the different parts of a tissue forming part of an organ. In stable equilibrium the removal of a portion of tissue leads to a proliferation of the neighbouring portions which continues until the deficiency is made good and then ceases—*regeneration*. Corresponding to this in the unstable condition we have a *tissue tumour* which consists of an overgrowth of a limited portion of tissue.

Again, there is a condition of equilibrium between the amount of the essential tissue and that of the supporting tissue of an organ. In the stable condition atrophy of the essential tissue leads to an increase of the supporting tissue as is seen in *replacement fibrosis*. The corresponding progressive process to this would be *progressive fibrosis* such as is seen in the fibrosis of nerves, and, possibly, in some forms of cirrhosis of the liver.

Next, there is a condition of equilibrium between the structure of a tissue and the function which it has to perform, both in quantity and quality. In the stable condition any increase of function leads to a corresponding hypertrophy of the tissue; this is *secondary compensatory hypertrophy*. I call it secondary because the primary change in the tissue in this case is hyperergia; examples are seen in muscles and glands. If the function which a tissue has to perform be altered in character the structure of the tissue also undergoes a change to enable it to fulfil its new function. This is *compensatory metaplasia*. If, for example, a surface covered by columnar epithelium is exposed to friction the epithelium undergoes metaplasia and is changed into stratified squamous epithelium. If, again, a tendon, the structure of which is only adapted to withstand a tension in the direction of its fibres, is called upon to support a stress at right angles to that direction, its structure becomes modified by the formation in it of cartilage or bone. Examples of this are found in sesamoid bones, drill bones, &c. The corresponding process in the unstable condition is *progressive metaplasia* such as is seen in myositis ossificans.

In the next place, there is a condition of equilibrium between the size of the different organs. If the equilibrium is stable and is disturbed by removing a portion of an organ or one of a pair of organs, the remaining portion undergoes *compensatory hypertrophy*. Whether or not a true primary compensatory hypertrophy, as distinct from the secondary form, exists, seems to be a matter of doubt—at any rate after intra-uterine life. The corresponding process in the unstable condition is *progressive hypertrophy*, examples of which condition are seen in the prostate, breast, thyroid gland (goitre), bones (leontiasis ossea), and perhaps in the lymphatic glands in Hodgkin's disease. The hypertrophy in these cases is not accompanied by hyperergia

Lastly, there is a condition of equilibrium between the functions of the different organs. Diminution of the function of an organ leads to *compensatory hyperergia* of a similar or correlated organ Corresponding to this we have, in the unstable condition, *progressive hyperergia*, examples of which are found in the kidneys (diabetes insipidus), leucocyte-forming organs (leucocythæmia), and, perhaps, in the thyroid gland in Graves's disease. Hyperergia, whether compensatory or progressive, is followed by secondary compensatory hypertrophy.

We see from the foregoing considerations that diseases may be divided into two great classes: (1) those which occur in a body in which the condition of equilibrium is stable; and (2) those which occur in a body in which the equilibrium is unstable The pathological processes which characterise the diseases of the first class all tend towards the restoration of the original position of equilibrium, while those which are characteristic of the diseases of the second class have a progressive tendency away from the original position.

I have omitted all mention of the retrogressive processes, but on examining these we find that, in the same way, some are characteristic of stable, others of unstable equilibrium. The former are due to definite causal factors which are extrinsic to the part concerned; they cease on the removal of this factor and restoration takes place. The latter are not characterised by definite extrinsic factors and restoration does not occur. We can, in fact, liken the organism, the cells, tissues, and organs of which are in stable equilibrium to a nation composed of individuals bound together by a well-ordered government and various moral forces, and living together in harmony and prosperity, each individual doing his own work and propagating his own species. In such a community if an attack were threatened from without those at the point attacked would first resist the invaders and if these were unsuccessful the whole number of individuals would take their share in defence. On the other hand, an organism, the component parts of which are in unstable equilibrium, can be likened to a nation of individuals discontented with the government and at variance with each other. In such a case a very slight attack from without would suffice to kindle a rebellion on the part of the discontented faction which would tend towards the destruction of the nation. The same effect might easily occur, without any extrinsic interference, from intrinsic causes alone. Thus the reparative processes constitute a defence of the organism against extrinsic injurious agents, while the progressive processes constitute a rebellion on the part of certain components against the mastery of the body as a whole. What, then, are the forces between which this equilibrium exists? We can represent them diagrammatically in the following way:

FIG. 2.

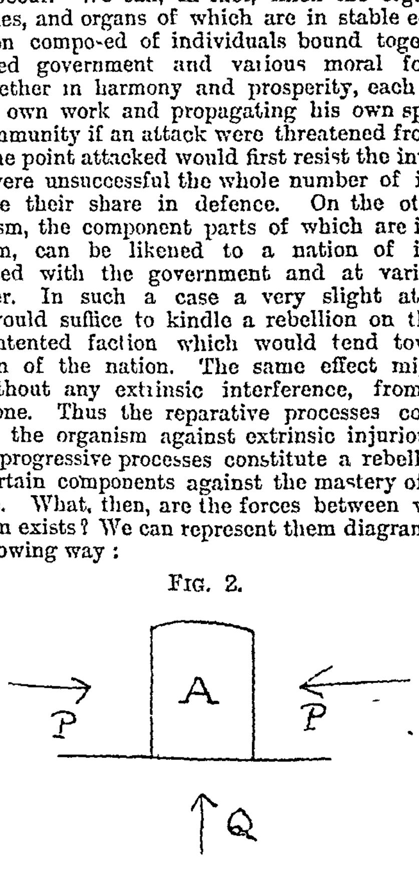

FIG. 3.

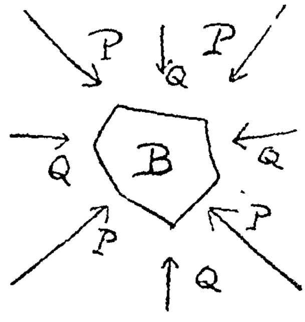

Let A (Fig. 2) represent an epithelial cell. This cell possesses an intrinsic tendency to proliferate in all directions. This tendency is kept in check by certain forces P exerted by the epithelial cells adjacent to it and by the force Q exerted by the subjacent connective tissue. Under normal conditions the tendency to proliferate and these intercellular forces are in equilibrium. As the tendency to proliferate in the direction of the free surface is not counteracted by any intercellular force proliferation may

## LECTURE III.[1]

*Delivered on Feb. 14th.*

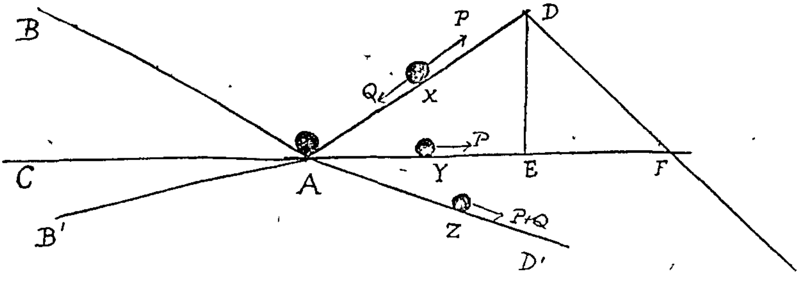
MR. PRESIDENT AND GENTLEMEN,—In the preceding lectures I have considered the classification and life-history of tumours, and I have reviewed various theories which have been advanced to explain their causation I now propose to consider the relation of tumour formation to other pathological processes

### PHYSIOLOGICAL EQUILIBRIUM.

The various parts of which the organism is composed are normally in a condition of equilibrium; that is to say, each component exists in such a position and quantity as is best suited for the useful performance of its functions, and the functions themselves are also in equilibrium. The position of equilibrium—that is, the exact relation between the component parts—varies in different individuals and in the same individual at different ages. This condition of equilibrium we call *health*. If this condition of equilibrium is disturbed in any way by an alteration in the position, quantity, or function we have the condition known as *disease*. We can represent this by a mechanical illustration (Fig. 1).

Let B A C, D A E, be two inclined planes, the angles at A being equal and the inclinations of the planes being in opposite directions. Let D F E be a third plane sloping from D in the opposite direction to D A. A position of equilibrium—that is, a condition of health—is represented by a ball resting on the planes at A, all forces acting on the ball being supposed to act in the plane of the paper, which is considered vertical. The condition of disease will be represented by a displacement of the ball up the plane A D to a position X, in which it is no longer in equilibrium. At X the ball is acted upon by two forces (neglecting the resistance of the plane), the disturbing force P acting up the plane, which represents the extrinsic cause of the disease, and the component of gravity Q (= W sin D A E, W being the weight of the ball), acting down the plane, which represents the tendency to repair. The stability of the equilibrium is measured by the force Q, and, since this is equal to W sin D A E, it is proportional to the sine of the angle D A E. If this angle is positive—that is, if the planes are above the horizontal line C A E—Q acts in the direction down the plane towards A. If the angle D A E is zero—that is, if the planes are in the position of the horizontal line—Q = O and the condition is one of neutral equilibrium in which there is no tendency to return towards the original position A. If the angle is negative—that is, if the planes are below the horizontal line in the positions A B′, A D′—Q is negative and acts in the same direction as P, and the condition of equilibrium is unstable, there being no tendency to return to the original position A but a tendency to move farther and farther away from that position, this tendency being independent of the disturbing force P.

FIG. 1.



Now, corresponding to these two conditions of stable and unstable equilibrium we have two groups of pathological processes—the *reparative processes*, such as repair, compensatory hypertrophy, and compensatory hyperergia; and the *progressive processes*, such as tumour formation, progressive hypertrophy, and progressive hyperergia. The characteristic of the reparative processes is that there is a tendency to return towards the original position of health, while in the progressive processes the tendency is to fall more and more away from that position. We can, therefore, represent a disease characterised by the reparative processes, such as an inflammatory disease, by the position X, P being the irritant and Q the tendency to repair. If P be the greater the ball will ascend the plane and in time may arrive at a position such as D, in which any further displacement will cause it to run down the plane D F. If, however, Q be the greater the ball will return towards A. That is, if the irritant overcomes the tendency to repair the disease will extend and may ultimately give rise to a progressive process such as a tumour arising in a chronic ulcer. If, however, the irritant is overcome by the process of inflammation repair sets in and health is restored. It is obvious that, for a given force P, the amount of displacement of the ball depends on the stability of the system, and in the same way the reaction of the body to an irritant depends on the stability of the individual, some patients being immune and others extremely susceptible to the same irritant. A disease characterised by a progressive process is represented by the position Z in which the tendency is for the disease to extend progressively.

In the reparative processes, although the tendency is always to return to the original position of health, yet this position is seldom exactly regained, the position of equilibrium itself being altered more or less according to the intensity or duration of the disturbing factor. This alteration of the original position is indicated, in the healing of a wound for instance, by the presence of a scar. Under certain circumstances the original stable position may become unstable, as is seen in tumour formation in a scar. This might be represented in the diagram by supposing that the force P did not act directly up the plane, but acted more horizontally so as to press the ball against the plane and thereby to depress the latter so as to bring it eventually into the position A D′ The diagram also shows that under stable conditions the disease will extend so long as the extrinsic force P continues to act, while *in the unstable condition* the extent does not depend on the extrinsic force but only on the intrinsic.

Now this condition of equilibrium exists between different parts of the body. Firstly, there is a condition of equilibrium between the component parts of the various tissues, that is, between the cells and intercellular substance If the condition is stable and is disturbed—e.g., by injuring the tissue—the cells at first proliferate out of proportion to the intercellular substance; these cells then lay down the intercellular substance and thus restore the and Sir William Bennett, in the lecture to which I have previously referred, described two cases in which mental concentration directed to the breast seemed undoubtedly to have taken part in the causation of tumours in that situation. Age also plays a part especially in the causation of carcinoma, and the observations of Thiersch, Woodhead, and others have shown that it acts through the relative atrophy of the connective tissue compared with the more active epithelium.

---

[1] Lectures I. and II. were published in THE LANCET of Feb. 15th, 1902, p. 423.

The influence of heredity on the causation of tumours has been variously estimated and I do not propose to go into the statistics on this point. There can, I think, be no doubt that heredity has a share in causation, but it is not the tumour, but the unstable condition of equilibrium, which is inherited. The extent to which the body cells proliferate in normal development and growth is undoubtedly inherited and, since errors of development are admitted to be inherited to a certain extent, it is probable that errors of growth, such as tumour formation, may be also. Tumours, however, may be congenital without being inherited and are, in this case, apparently due to a defect in the normal heredity of structure. Just as there may be a defective development of an organ, so there may be a defective development of the intercellular forces. The part which heredity plays in tumour causation differs from the part that it plays in the causation of such diseases as tuberculosis in the fact that in tumours the essential factor—namely, the unstable condition of equilibrium—may be inherited, while in tuberculosis it is the adjuvant factor, the susceptibility, which is transmitted.

An important factor in tumour causation is to be found in the influence of civilisation. Cancer is admittedly more common among civilised nations than among uncivilised, and it is more common among domestic animals than among those that are wild. Civilisation acts probably by means of the unnatural mode of life which it entails. Indoor life, sedentary occupations, excessive feeding, unnatural clothing, the mental worry and excitement which are inseparable from such a life all play their part. It is to these factors that we must look for an explanation of the alleged increased frequency of cancer at the present day.

It is not to be supposed that the equilibrium throughout the body is in an unstable condition. The instability sometimes affects the whole of one tissue in an organ, as in the case of diffuse sarcoma and carcinoma, but it is usually limited to a much smaller area, to a minute piece of tissue or even to a single cell or group of cells. While, then, this instability explains the occurrence of the primary tumour, it will not explain its extension to surrounding parts nor will it explain the occurrence of metastasis.

There are certain bacteria which at first grow with great difficulty on artificial media; by frequent transplantation, however, they acquire the property of growing readily on such media and this property is transmitted to their descendants. In the same way the cells of a tumour by continuous proliferation in the primary growth acquire an increased power of proliferation which power is handed on to their descendants. If, then, these descendants arrive in a region in which the equilibrium is stable, they are able to proliferate in spite of the resistance offered to them and so to give rise to tumour growth. This increased power of proliferation is called by Adami the habit of growth. Once the cells have acquired this habit they behave as independent parasites. This explanation of malignant disease—namely, that the cells themselves act as parasites—will explain how it is that tumours are, as a rule, only infective among animals of the same species, since it is known that the blood of an animal can be replaced by that of another animal of the same species, but not by that of an animal of a different species; transplantation of tissues, also, is only successful between animals of the same species.

As I have mentioned previously, the wasting and cachexia of malignant disease can probably be explained by the destruction of tissue and the drain of nutriment by which it is accompanied, especially by the loss of carbohydrate material. Absorption of the products of degeneration may also take part in the causation of these conditions. This view of the pathology of tumour formation is based on the groundwork of observed facts and will explain all the phenomena associated with tumour growth.

### SUMMARY OF CONCLUSIONS.

I would sum up my conclusions as to the pathology of tumour formation as follows: 1. Tumours are to be classified on a histological basis. The best mode of effecting this is to make use of the three-fold basis of cells, tissues, and organs. 2. The rudiment from which a tumour springs may consist (1) of the structures normally present at the point of origin; (2) of an embryonic collection of cells such as is described by Cohnheim; or (3) of tissues of new formation, the result either of an inflammatory condition or of previous tumour formation. 3. Extrinsic factors play a part in tumour causation, but are not the determining factors—that is, the occurrence or non-occurrence of a tumour does not depend on extrinsic factors. In particular, the parasitic theory is shown not to stand a critical investigation. 4. The determining factor in tumour causation is to be found in the intrinsic factors. 5. This determining factor consists in the existence of a condition of unstable equilibrium between the intercellular forces, so that proliferation, once started, is progressive and is not limited by the resistance of the surrounding tissues. 6. The causes of this instability are many and various and may be either intrinsic or extrinsic. 7. Proliferation having started, the cells acquire the habit of growth—that is, the power of independent proliferation which enables them to proliferate in parts of the body in which the condition of equilibrium is stable. 8. Tumours grow by proliferation of their own cells. 9. Tumours do not invariably continue to increase without limit. Under certain circumstances they may cease to grow and may diminish in size or may even disappear completely. 10. Tumour formation is not to be regarded as an isolated process but is to be considered as one of a group of progressive processes with which it is closely allied. Still less must one form of tumour, such as carcinoma, be considered apart from the others.

### INDICATIONS AS TO TREATMENT.

It is not my duty as a pathologist to enter into details regarding the treatment of tumours, but we must remember that the three divisions of practical medicine and surgery—namely, pathology, clinical observation, and therapeutics—are mutually interdependent. The pathologist learns much from the clinician and the therapeutist and in return can render them assistance by suggesting modes of treatment. It is one of the most important duties of pathology to point the way to new methods of diagnosis, prognosis, and treatment, and without this it would have no practical utility.

If we refer to our mechanical illustration (Fig. 1) we see that when the ball has been displaced to the position X it can be brought back to its original position by two methods—either by removing or diminishing the extrinsic force P or by increasing the force Q. Since the force Q depends on the angle D A E, we can increase the force Q by increasing this angle. Similarly in disease we can either remove the extrinsic causes or we can increase the resistance of the body so as to enable it to overcome these causes. We can also act upon any intrinsic factor that may intervene between the extrinsic cause and the ultimate effect. In the case of tumours and the progressive processes generally, since we have to do with an active cellular proliferation we can hinder this by diminishing the supply of nutriment.

I have pointed out that the extrinsic factors in tumour causation are many and various and that they only act in initiating the disease. The removal of these factors, therefore, will act mainly as a prophylactic. For this purpose all sources of irritation, whether mechanical, parasitic, chemical, or the result of inflammatory conditions should be removed or avoided, especially in the case of those who show a propensity to tumour formation, such as those from whom a tumour has already been removed. This mode of treatment has, obviously, only a limited application. By removing the tumour we remove at once the area in which the condition of equilibrium was unstable and the cells which have acquired the habit of growth. In the case of simple tumours this mode of treatment will effect a permanent cure, and the same will be the case with a primary malignant growth if the removal is complete—that is, if all the cells which are the result of the tumour growth are removed so that none are left to find their way to distant parts of the body to give rise to metastatic tumours. This method of treatment is, and will remain, by far the most important, both with simple and malignant tumours. Unfortunately, it is not common to meet with malignant growths in a sufficiently early stage to enable us to be certain of effecting their complete removal, and after removal it is practically impossible, even after a minute histological examination, to be quite sure that all the proliferating cells have been removed.

take place in this direction In the case of secreting cells however, proliferation towards the free surface is replaced by secretion If, now, we remove one of the forces P, as by removing the neighbouring epithelial cells, proliferation is set free in the direction of the removed force The same will be the case if one of the forces P be diminished instead of being removed, as is the case in the epithelial cells lining a retention cyst If the original condition of equilibrium was stable the force P will be restored by the proliferation and the equilibrium will be regained *This is the case in* regeneration of epithelium following a wound &c. If how ever the equilibrium was originally unstable the force P will not be restored and proliferation will continue, thus giving rise to an epithelial histioma If the force Q be removed or diminished proliferation will take place into the subjacent connective tissue In this case if the original condition was *stable the force Q would be restored and proliferation would* cease If, however the equilibrium was unstable, the force Q would not be restored and proliferation would continue in the connective tissue giving rise to a carcinoma

Again let B (Fig 3) represent a connective tissue cell This cell has a tendency to proliferate in all directions, which tendency is kept in check by the forces P exerted by the neighbouring cells of the tissue and also by certain forces Q representing the influence of the intercellular substance If the forces P are diminished or removed, the forces Q remaining the same proliferation will take place and will be accompanied by the formation of the normal amount of intercellular substance This will give rise, in the stable condition to regeneration of the tissue , in the unstable, to a histioma consisting of the same kind of tissue If on the other hand, the forces Q be diminished proliferation of the cells will occur but the intercellular substance will not be formed in the proper amount and this will give rise in the unstable condition to a sarcoma and, in the stable condition, it is seen in the proliferation which is characteristic of repair The other processes to which I have referred might be represented in a somewhat similar manner

As to the nature of these intercellular forces we have no knowledge They are apparently not the recognised physico chemical forces nor are they nervous although the nervous system may have an effect in regulating them Development proceeds regularly and uniformly under the influence of these forces before the existence of nervous connexions the different tissues developing in their proper situations and of their proper structure according to the part which they have to play in the organism The more we study the growth and development of living organisms the more difficult it is to believe that vital phenomena can be explained on a physico chemical basis The intercellular forces may be altered directly by extrinsic agents such as irritants, but being intrinsic forces they may also be affected by intrinsic factors *without the direct action of external agents*

### CAUSATION IN GENERAL

A cause is defined by logicians as the invariable unconditional antecedent of an event which in relation to the *cause is called the effect A cause is said to have five* characteristics it is quantitatively equal to the effect and qualitatively it is invariable unconditional, immediate, and antecedent Cause in this sense is the sum of all the conditions which are necessary for the occurrence of the event A cause it is to be noticed is not a definite entity, but is a state or process , it is essentially matter in motion The equality of cause and effect follows from the principles of the conservation of energy and the indestructibility of matter The effect is in fact the cause redistributed , hence it follows that any substance which forms part of the cause must also be found in some form or other, in the effect For any given event there is only one cause and a given cause gives rise to only one effect. We can, however, consider the cause itself as an effect and proceed to inquire into its causation We thus arrive at intermediate and remote causes but the farther we proceed the more conditions we introduce We can *thus divide causes into immediate* and remote, the remote being connected with the immediate by a series of intermediate causes Of these the only unconditional cause is that which is immediate remote causes being always conditional In the remote causes there are, however certain essential factors present

To take an example let us consider tuberculosis This disease is defined at the present day as a disease caused by the bacillus tuberculosis and the only certain method by which we can say that a given disease is tuberculous is to demonstrate the presence of the bacillus The immediate cause is therefore the action of the bacillus on the living tissues If we proceed a step farther and inquire into the cause of this action we find that it is the entrance of the bacillus into the tissues with the condition that the tissues must be capable of being acted upon by the bacillus, or, in other words that the tissues must be susceptible We can proceed step by step in the same way and arrive at more remote causes but however remote the cause there must always be *present the essential factor—namely, the bacillus* itself Tuberculosis is therefore a disease characterised by an essential causal factor which is of extrinsic origin

To take another example, let us consider carcinoma. The characteristic feature in carcinoma is the presence of proliferating epithelial cells in the connective tissue spaces In carcinoma therefore, there is no necessary extrinsic factor *present corresponding* to the bacillus of tuberculosis and from the equality of cause and effect there can be no necessary extrinsic factor in the cause of carcinoma The immediate cause of carcinoma is the disturbance of an unstable position of equilibrium between the epithelial cells and the connective tissue so that the epithelial cells penetrate into, and proliferate in the connective tissue, the essential factor—namely the instability—being intrinsic The immediate cause of carcinoma is therefore, an intrinsic one and involves no extrinsic factor

### ETIOLOGY OF TUMOURS

In considering the causation of tumour formation we must take into consideration the peculiarities of tumours In the first place tumours are local overgrowths and in the second, this overgrowth is progressive—that is, *it is not limited by* the influence of the surrounding tissues Now the growth in tumours does not differ essentially from that of normal structures and there is no reason to suppose that the cause of the proliferation is different in the two cases Cell division is as Adami states an intrinsic property of the cell and is only influenced indirectly by extracellular conditions The usual *conditions* which give rise to proliferation are injury or removal of the neighbouring cells thus producing an altera*tion of the intercellular forces acting on the cell Increased* functional activity and increased blood supply also give rise to proliferation In addition these intercellular forces may be altered by intrinsic conditions

The progressive nature of the growth in tumours shows that the original condition of equilibrium of the part in which the tumour arose was unstable so that the growth once started is not opposed by the normal intercellular forces This instability is the determining factor of tumour formation and the other progressive processes as in its absence no amount of extrinsic irritation would give rise to them In this instability of equilibrium then we have found that for which we have been seeking namely, the common factor of tumour formation The cause then of the progressive processes is the disturbance of a part of the body the component elements of which are in unstable equilibrium This satisfies the necessary qualitative conditions of a cause , it is immediate unconditional invariable, and antecedent and it is the only cause which satisfies these conditions any remoter cause being conditional If we proceed to look *for the causes of this instability—that is for* the remote causes of tumour formation &c —we find that they are many and of various kinds They may be the same as those which cause the disturbance of the equilibrium or they may be different Chronic irritation is a frequent cause, this may be mechanical as *in the irritation of a tooth or as* in soot and paraffin cancer, or it may be parasitic as in the carcinoma arising in lupus nodules and in the bladder tumours which are sometimes met with in bilharzia disease Dr T Harris[2] of Manchester has described a case of carcinoma associated with bilharzia irritation in which the ova were found not in the tumour itself but in the tissues of the bladder wall in the neighbourhood The ova had given rise to a chronic irritation which had produced a condition of unstable equilibrium with the formation of a tumour as a result Besides these extrinsic causes, which, it will be observed have no specific characters there are also intrinsic causes. The great frequency with which the female *organs of generation* are the seats of tumour formation is to be explained by the frequent alternations of rest and activity to which these organs are subject Tumours have often been attributed to mental worry and similar conditions,

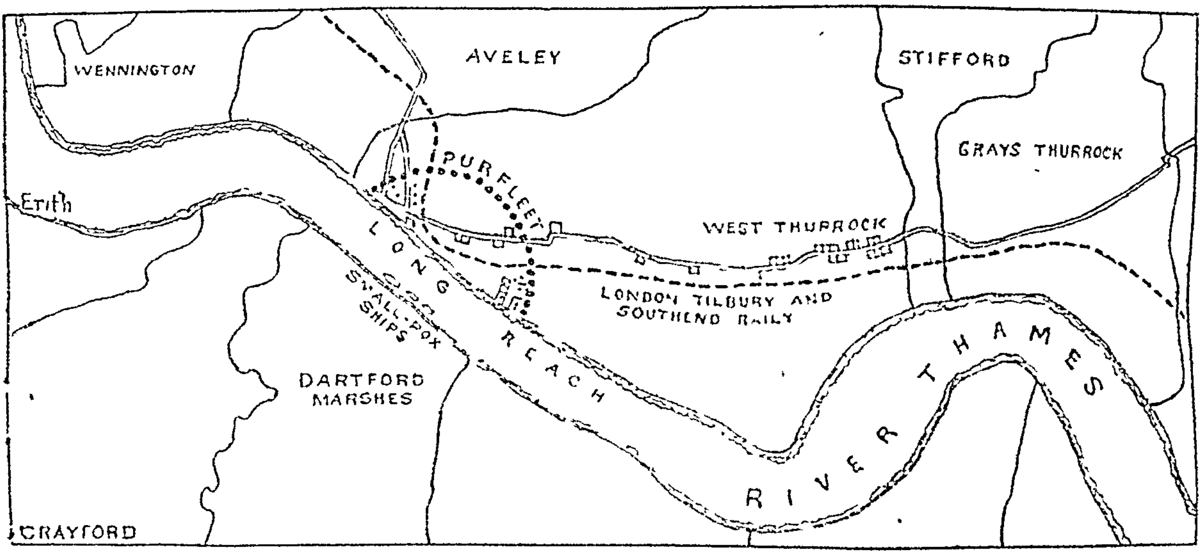
FIG. 1.



Map showing the position of the hospital ships in the Thames in relation to Purfleet and West Thurrock. The dotted line includes Purfleet.

in 1884. Prior to this time I cannot ascertain that there was any unusual incidence of small-pox in this hamlet, but, as the following figures show, the disease was more prevalent, as indicated by the death-rate, in the Orsett Union than in other parts of Essex. This is probably due to the fact that vaccination has until recently been very lax throughout the union.

TABLE I.—*Deaths from Small-pox in the Orsett Union and in the Remainder of the County of Essex.*

| — | Orsett Union. | Remainder of the county. |
|---|---|---|
| Number of deaths from small-pox, 1871–1883 inclusive . .. . ... | 25 | 389 |
| Annual death rate per 1000 ... .. | 0·117 | 0 089 |
| Number of deaths, 1884–1900 inclusive .. .. .. ... . ... | 33 | 116 |
| Annual death rate per 1000 . ... | 0 072 | 0 014 |

It will be seen that since 1884, when the floating hospital was placed in the Thames, the deaths in the Orsett Union from small-pox have proportionately greatly increased. The ratio which in the first period was 4 to 3 has since been 5 to 1. To what is this change attributable if not to the proximity of the ships?

The accompanying map shows the position of the floating hospital in the Thames, relatively to Purfleet and West Thurrock parish in the Orsett Union. Within the half-mile radius of the ships there are only about four cottages on the Essex side of the river, whilst the three-quarter mile radius includes all the hamlet of Purfleet which is a portion of the parish of West Thurrock Beyond this limit the only groups of houses are in West Thurrock on the road to Grays. At Purfleet there are paper-mills, oil-stores, &c., employing many hands, some of whom reside at Grays. In investigating the cases which occurred during 1892-95 there was no evidence of infection from these works or from the rubbish-tip used by a London vestry. During these years 15 cases occurred in the Purfleet area, 28 in the remainder of the West Thurrock parish, and 52 in the rest of the union. The relative prevalence is given in Table II.

TABLE II.—*Relative Prevalence of Small pox in certain Districts of the County of Essex.*

| — | Number of cases. | Proportion relatively to population, Purfleet being taken as 100. |
|---|---|---|
| Purfleet ... . .. . . | 15 | 100 0 |
| West Thurrock (whole of) . | 35 | 46 0 |
| Orsett Union without West Thurrock | 48 | 7 0 |
| Essex County without Orsett Union | 658 | 3·5 |

Within the three-quarter mile radius from the ships cases were twice as numerous in proportion to the population as in the whole of the parish of West Thurrock, 14 times as many as in the remainder of the union, and 30 times as numerous as in the remainder of the administrative county. In other words, the further the district from the ships the less the number of cases. The aerial conveyance of infective material alone appears to account for this excessive prevalence.

TABLE III.—*Progress of Small pox in the County of Essex for the period extending from August, 1901, to January, 1902.*

| — | Population. | 1901. August. | September. | October. | November. | December. | 1902 January. | Total. |

Seeing that proliferation of cells plays the important part in tumour formation, it is natural to ask whether it is possible to hinder the proliferation by any process of starvation Starvation might be induced, either by a general reduction of the nutriment supplied to the body, or by a local cutting off of the nutriment such as is effected by ligature of the arteries which supply the tumour with blood We should not expect much from the first method since the other tissues would be equally affected by the deficiency of nutriment The second method has been tried in some cases of inoperable carcinoma with the effect of temporarily diminishing the rate of growth

I have previously referred to the presence of large quantities of glycogen in tumours, especially in those which are malignant This glycogen is found wherever active proliferation is taking place and it supplies the energy necessary for the proliferation The question arises therefore whether we can control this supply in any way In glycosuria we know that the carbohydrates excreted in the urine may be derived either from the ingested carbohydrates or from the proteids of the body The origin of the glycogen in tumours has not been investigated so fully, but probably the same two sources are available as in diabetes An examination of the quantity of nitrogen excreted in the urine would be of assistance in determining this point but I am not aware of any systematic investigations in this direction The urine in malignant disease has not received the attention that it deserves The presence of wasting and cachexia would seem to show that the proteids of the body are broken up and it is very likely that the glycogen arises, in part at least from this destruction of proteid matter If this is the case we cannot expect much from a carbohydrate free diet since the body proteids would still remain as a source of the glycogen Is it possible then to remove the glycogen which has been formed? We know that malignant disease is very rarely met with in association with diabetes and we also know that in acute diabetes wounds heal with great difficulty The explanation of this is probably that the glycogen which is necessary for the proliferation of cells is continuously being removed from the body as glucose It is permissible, then, to think that by setting up an artificial glycosuria we could remove the glycogen as fast as it is formed and so prevent it being available for supplying the energy necessary for the proliferation of the tumour cells Such a glycosuria may be set up by means of certain drugs—such as phloridzin This is a point which might well be investigated by therapeutists I am afraid, however, that we must not expect much from such a treatment because the drug would remove the glycogen from the normal tissues as well as from the abnormal and it would be of little use to hinder the progress of a tumour if the surrounding tissues were not able to take advantage of the occasion by reacting and absorbing it Much depends on the question whether the normal or the abnormal tissues would yield up their glycogen most readily

The most important question at the present time with regard to malignant disease is whether anything can be done to prevent or to retard recurrence and metastasis and to benefit inoperable cases As I have pointed out, tumours are essentially due to intrinsic causal factors, and any treatment should therefore be directed towards these factors The cases described by Sir William Bennett, to which I have referred and numerous other recorded cases, show that malignant disease does not always proceed to a fatal termination but may become arrested and even cured To facilitate this course measures should be taken which would raise the enfeebled resistance of the body tissues In this connexion I may mention that arsenic which has a markedly tonic action has been recommended in all diseases characterised by the progressive processes and in some cases with some degree of success At a recent meeting of the French Académie de Médecine Dr Lucien le Roy[3] gave an account of a case of cancer of the lung in which the patient apparently recovered after treatment with arsenic and quinine The details of this case are not yet published Coley s fluid probably acts in the same way by producing an increased reaction of the surrounding tissue against the tumour and the same may, perhaps be said of such procedures as oöphorectomy and feeding with thyroid extract This last mode of treatment has been recently reviewed by Mr H. T Butlin[4] who comes to the conclusion that the benefit derived from it is only temporary

The immense improvement which has taken place in the treatment of tuberculosis points the way to a similar procedure in malignant disease This hygienic treatment acts by increasing the resistance of the body tissues to the encroachments of the tubercle bacilli and I think that it is worth while to consider whether by a similar mode of treatment the body tissues could be encouraged to resist with greater force the encroachments of the tumour cells I am inclined to think that if a patient from whom a malignant tumour has been removed, instead of returning to a sedentary and unhealthy mode of life were to lead an active outdoor existence in a healthy climate with sufficient exercise and good plain food leading as natural a life as possible, there would be less tendency for the disease to recur, and it is possible that a tumour already present might under these circumstances show a slower rate of growth or might even undergo a diminution

And now Mr President and Gentlemen, my task is ended I have laid before you no new hypothesis, nor have I brought forward any startling experimental results I have endeavoured to bring to your notice the facts mostly well known to you concerning the process of tumour formation and to show what conclusions we can legitimately draw from these facts and I have tried to point out to what modes of treatment these conclusions lead Finally, I would urge that the investigation of the pathology of malignant disease should not be left altogether to the bacteriologist Histologists, pathological chemists clinicians, and therapeutists should all take part for much remains to be discovered in all these branches of medical research There is especially a great field for work in the study of the clinical characters of malignant disease such as the temperature, the urine, and the phenomena of cachexia There is too much tendency at the present day to regard micro organisms as everything in the causation of disease and to neglect the personal or intrinsic factors I would also urge that the investigation should not be confined to the malignant tumours alone but should include other tumours and those processes which are allied to tumour formation It is only in this way that we can hope to arrive at any final conclusion as to the pathology of tumour formation

# THE HOSPITAL SHIPS OF THE METROPOLITAN ASYLUMS BOARD AND THE DISSEMINATION OF SMALL-POX

BY JOHN C THRESH, M D VICT, D SC LOND,
LECTURER ON PUBLIC HEALTH LONDON HOSPITAL MEDICAL COLLEGE
MEDICAL OFFICER OF HEALTH OF THE COUNTY OF ESSEX

THE excessive prevalence of small pox in the Orsett Union has for many years been notorious in the county of Essex Investigations made during the years 1892–95 led me to conclude that the sole cause of this excessive prevalence was the proximity of the small pox ships of the Metropolitan Asylums Board This was also the popular view From 1895 until the autumn of last year the county of Essex and the metropolis remained almost free from the disease During the quarter ending June 30th 1901 only six cases were notified in London but soon after there was a marked increase resulting in 272 cases being notified during the third quarter As soon as this tendency to spread manifested itself and the number of cases of small pox in the ships increased the opinion was openly expressed that an outbreak would speedily occur in the Orsett district and that as usual it would commence in Purfleet By the middle of September a few cases had occurred and since then cases have followed in rapid succession until now (Feb 1st 1902) about one tenth of the whole population in Purfleet has been attacked This outbreak soon spread to the town of Grays and to adjoining parishes and is gradually extending into all parts of the county The expense already incurred in providing accommodation for the patients is very considerable and in the Orsett Rural District it is almost ruinous The subject, therefore is of very great importance to the county

The small pox ships were anchored opposite Purfleet early four and a half miles from the ships. The disease once introduced into West Thurrock is carried by the men engaged at the cement and other works into Grays and other parishes. It has been surmised that the enormous volume of infected sewage poured into the river from the ships may explain the incidence of the disease in the parishes adjoining the river. Of this there is at present no proof. The evidence usually adduced is based on the fact that several men who have contracted the disease had been accustomed to bathe in the river. I am decidedly of opinion, however, that this sewage should be treated in some way before it is allowed to flow into the Thames.

[3] Brit Med Jour Jan 25th 1902

[4] Ibid Jan 4th 1902

I desire to express my indebtedness to my assistant, Mr. Sowden, who has collected for me a large mass of information with reference to small-pox prevalence in the Orsett Union, a portion only of which has been utilised in the present paper.

Chelmsford.

# ON CLEFT PALATE.

BY W. ARBUTHNOT LANE, M.B., M.S. LOND., F.R.C.S. ENG.,

SURGEON TO GUY'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

*(Concluded from p. 438.)*

FROM the consideration of the facts narrated in the previous article the indications for the treatment of the sufferers from cleft palate seem to me to be clearly as follows. First, we must endeavour to increase the vital capacity of the sufferers by teaching them how to breathe properly and efficiently. To do this the demand on the expenditure of energy should at first be reduced to the minimum requisite to fill and empty the chest to its utmost, avoiding any exercise of the muscles which does not bear directly in bringing this about. In this manner as much energy as possible is accumulated at a minimum of cost to the total energy or capacity for work of the individual. To make these children perform systematic exercises for purposes other than increasing the respiratory capacity is a most wasteful procedure and quite beyond that permissible by the amount of their usual income of energy. By increasing their breathing capacity you supply a proportionately larger quantity of oxygen, which enables them as individuals and their several tissues as component parts to perform physiological functions in a more satisfactory manner. The improvement can be gauged by measuring the daily progressive differences between the measurements in extreme inspiration and extreme expiration. Of course, the air breathed should be as good as possible. Secondly, the mouth must be kept shut habitually and certainly during the respiratory exercises air must be driven freely and forcibly in and out through the naso-pharynx alone. If any mucus exists in the nasal passages it must be cleared by blowing the nose vigorously. If this treatment is pursued efficiently and thoroughly the nasal catarrh is removed as well as the irritation and hypertrophy of the lymphatic tissues in the pharynx and there is increase of the lumen of the naso-pharynx with the bony and other structures directly dependent on its development for their complete evolution. The rate at which this result is obtained varies inversely with the chronicity of the condition and with the age of the child. The form of the alveolar arches and of the palate alters, the arch opening out in either case. The change in form which the whole face undergoes in consequence of the increase in size of the naso-pharynx and the cavities communicating with it is in some cases most remarkable, attracting at once the attention of those who have not seen the patient in the interval during which the treatment has been adopted. As to how this is best done must vary largely with the intelligence of parents, their perseverance, and the time and means which they have at their disposal.

In out-patient practice from the circumstances of the parents the treatment can rarely be carried out in the same effectual manner that is possible in private practice, where the patient is under the immediate control of the medical attendant who sees that his instructions are strictly enforced. In hospital work it is well to give the mothers a rinted form containing the following or similar instructions: 'Put the child on the back three times a day for half an hour at a time, and make it breathe in and [illegible] possible through the nose, the mouth being kept shut," and to endeavour to interest them in its application.

In the treatment of this condition, as of many others with which we are constantly confronted, in hospital practice measures have often to be adopted of a more serious nature and at an earlier period of the disease than would be considered advisable for one moment in the case of patients in comfortable circumstances, where the rest, care, and change that they could command would probably produce far better results in the long run. Among the better class of mothers, such as the wives of policemen and mechanics, results will frequently be obtained almost as good as those obtained in private practice; but the poorer portion of the community have neither the time nor the intelligence to follow these instructions, nor will they often devote their energies to the duty. The surgeon can readily determine whether his treatment is carried out efficiently or not by keeping a diary in which the differences between the measurements of the chest in extreme inspiration and extreme expiration must be entered daily. These daily observations will keep him informed of the degree of progress which his patient is making. Should this variation not show a steady increase in amount he can rest assured that his instructions are not being carried out properly.

One of the results of improving the respiratory capacity which is of considerable importance is the steady increase in weight which ensues. The following is a nurse's reports of the progress of a girl under her care for a month and it affords some indication of the results that can be obtained. The measurements are taken at the level of the nipples and represent the inspiratory and expiratory limits. They are certainly better than the average for the reason that every care was taken to make the treatment as effective as possible.

The treatment was continued uninterruptedly, being superintended by the sister of the patient, and on May 27th of the same year, four months having elapsed since it was started, the following report was sent me: Inspiration, 36 inches; expiration, 29½ inches; and weight, nine stones four pounds. This shows the following increases: Inspiration, six inches; expiration, one inch; and weight, one stone eight pounds.

As the respiratory capacity improves so the child obtains energy to spare, and it becomes more active in the full enjoyment of life. If this treatment is adopted under

The present epidemic has afforded me an opportunity of studying more carefully the effect of the floating hospital. The earliest case of small-pox recorded in the county last year was that of a man employed during the day at Purfleet but residing at Grays; this was in the last week in August. The progress of the disease in the county since is shown in Table III.

Grays Urban District forms part of the Orsett Union. The number of cases in this union is therefore 290, the population being 33,721; in the remainder of the county in which cases of small-pox have occurred there have been 162 in a population of 523,465, or taking the whole county save the Orsett Union 162 cases in a population of 782,700. Therefore, the cases per 1000 of the population in the Orsett Union were 8 6, while those in the remainder of the county were 0·21 per 1000. In proportion to the population there have been 40 times as many cases in the Orsett Union as in the remainder of the county.

The only centre of population within a mile of the hospital ships being the hamlet of Purfleet and the nearest parish being West Thurrock we should naturally expect these portions to have suffered most severely if the ships are the foci of infection. That this is the case can be demonstrated in a most conclusive manner.

Up to Feb. 1st there had been 290 cases of small-pox in the Orsett Union; 42 of these occurred in the hamlet of Purfleet within the three-quarter mile radius shown on the map, 50 in the remaining portion of the West Thurrock parish, and 198 in the other parishes of the union. In the following table the relative incidence of the disease in these districts is given, calculated on the basis of the last census returns and upon a census of the population made for the purpose by my assistant, Mr. G. Sowden:—

TABLE IV.—*Incidence of Small-pox in the Districts of Purfleet, the Remainder of West Thurrock, and the Remainder of the Orsett Union.*

| — | Purfleet hamlet. | Remainder of West Thurrock. | Remainder of Orsett Union. |
|---|---|---|---|
| Population ... .. ... .. | 479 | 2106 | 30,578 |
| Cases of small pox ... ... | 42 | 50 | 87 |
| Rates per 1000 of the population .. . .. ... | 88 | 24 | 2·8 |

It will be seen that nearly four times as many cases (in proportion to the population) have occurred in Purfleet as in the remainder of West Thurrock and 30 times as many as in the rest of the Orsett Union, notwithstanding the epidemic prevalent in Grays The next table, showing the condition of the population with reference to vaccination, proves that there is nothing in this to account for the extensive and persistent character of the outbreak.

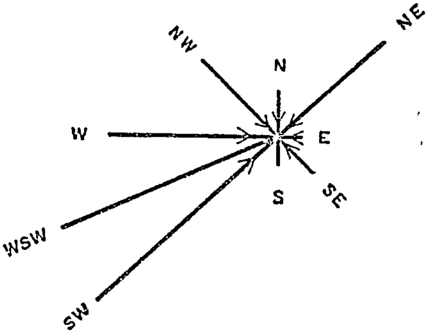
TABLE V.—*Statistics of Vaccination in Purfleet.*

| — | Vaccination in infancy only | Vaccination in infancy and since revaccinated | Not vaccinated but had small pox. | Neither vaccinated nor had small pox. | Total. |
|---|---|---|---|---|---|
| Adults ... | 111 | 171 | 8 | 4 | 294 |
| Children 12 years of age and under ... | 70 | 106 | 2 | 7 | 185 |

Moreover, the Orsett Rural District and the Grays Urban District possess a joint hospital (some miles from Purfleet) which was promptly used for the reception of patients. From my own observations I am convinced that more was done in this district than is usually done in such districts for preventing the spread of the disease, but these efforts have been futile since the focus from which the disease is being spread still remains.

There is only one other parish in the Orsett Union which is near the hospital ships This is Aveley with a population of 1061. During the period under consideration 22 cases have occurred in this parish, or 11 3 per 1000 of the population—a further confirmation of the air-borne character of the infection

FIG. 2.



Wind rose, August 18th, 1901, to Jan. 31st, 1902, showing prevalence of south-westerly winds.

Still more cogent proof, however, is obtained when the relation between the prevalent wind and the distribution of the disease is considered. The wind rose shows that by far the most prevalent wind has been from south-west and west-south-west and would therefore blow over that portion of Purfleet to the south of the railway. (See map.) Between the cottages here and those to the west of the railway there is a considerable area upon which there are very few houses. To the west of the railway there is a group of 32 houses lying almost due north of the ships. On very few occasions has the wind blown in this direction, hence if the infection is air-borne the inhabitants of this portion of Purfleet should have almost escaped. This is exactly what is found. In West Purfleet, with a population of 137, there has been only one case, whilst in South Purfleet, with a population of 342, there have been 41 cases The attacks in West Purfleet were 0 8 per 100, while in South Purfleet they were 12·0 per 100. In other words, in the cottages nearest and exposed to the prevailing wind out of every eight persons one has been attacked. If such an epidemic prevalence had occurred in London there would have been over half a million cases during the past seven months

In connexion with this outbreak in Purfleet it is interesting to note that out of the adult population, containing 12 who had not been vaccinated prior to the commencement of the epidemic, eight persons had had small-pox, and three have contracted the disease during the epidemic Amongst the children were nine who were unvaccinated; one had had small-pox some two years ago, two were too young to be vaccinated, and of the remaining six five have since contracted small-pox Taking both adults and children (excluding the two infants) there were 19 unvaccinated persons, of whom nine had had the disease before the epidemic, leaving 10 who had neither been vaccinated nor had had small-pox Of these eight, or 80 per cent., have contracted the disease during the past seven months.

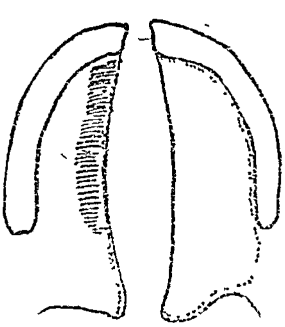
When cases were occurring in Purfleet in 1895 and the attention of the Metropolitan Asylums Board was directed to this fact the opinion was expressed that this was due to the proximity of the ships. It was then suggested, however, that the infection was spread by personal contact with visitors and others passing to and from the ships. This intercourse was stopped and for years past, I am informed, there has been no intercourse whatever between the ships and the Essex shore. Any infection, therefore, from the ships must have been air-borne

Besides the cases referred to of residents in West Thurrock I have notes of 15 others, persons engaged in works there but residing in Grays, Aveley, and Rainham. The last-named parish is in the Romford Rural District but is within a four-mile radius of the ships to the north-west.

It is exceedingly difficult to ascertain to what distance the infection may be carried by the air, but my impression is that in the direction of the wind it may be carried two, or possibly three, miles. I doubt very much whether the influence extends as far as Grays which lies from three to patient's intonation is peculiar, or, as it is usually called, nasal, is that the outgoing air does not pass through the nose, and when the cleft is closed at the usual time there is in the extremely undeveloped nose very little space through which air can be transmitted, and as far as I am aware no effort is made by surgeons to develop this space after operation. This is probably due to the fact that they had not considered the mechanics of this channel. If, however, the space is systematically and forcibly ventilated the calibre of the naso-pharynx is increased, and a considerable proportion of air passes through it, so that the so called nasal character of the voice is diminished very greatly. Still, assuming this statement and the preceding to be absolutely correct, in what light are we to regard the next? "Of primary importance is the question, At what age should the operation be performed? It may, I think, be laid down that whilst it is never wise to operate upon the child under three years of age the time of election is from this age up to six years." If we allow the second and third statements to be true, as they are approximately so, it is difficult for the ordinary mind to grasp the logical sequence of the conclusion deduced from them. The treatment of cleft palate, like the greater part of surgery, has been a matter of creed and tradition and has not been arrived at in any reasonable manner. In order to treat these cases as efficiently as possible no time whatever should be lost in restoring to the nose its normal physiology, or, in other words, in giving back to it the mechanical factor which alone determines its development and that of the other structures dependent on it to a considerable extent for their normal form.

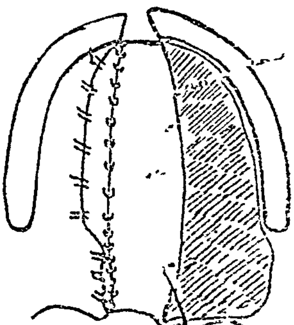
There are next for consideration the following questions—viz.: 1. What is the best age for operation? 2. What is the best method of performing the operation? 3. How and when can any complication such as harelip be met to the greatest advantage?

FIG. 16.



A complete cleft of the palate. The dotted lines indicate the incisions, and the shaded area the portion of muco periosteum elevated from the subjacent bone.

FIG. 17.



-ease i
-ting
at
in t.
d. A

The flap fixed in position by a double row of sutures. The shaded part shows the surface of hard palate stripped of muco-periosteum.

1. *Age.*—I find that as a rule the best age for operative interference is during the fourth or fifth week, providing that there is no special indication to the contrary, by which I mean bronchitis, diarrhœa, and the results of bad feeding [illegible]lly. Under such circumstances it is necessary to postpone the operation till the condition of the child is satisfactory. At the same time if the child is a vigorous and [illegible] I prefer to operate as soon after birth as possible. The advantages of operating at this early period are: (1) that the child bears the operation very well; (2) that but slight subsequent discomfort is experienced and the child will take food with satisfaction within an hour or two of the operation; and (3) that the amount of hæmorrhage is very slight and is easily controlled.

2. *Method of operating.*—Though the details of the operation must vary considerably in a small proportion of the cases, in a large number I endeavour to raise a flap of mucous membrane and periosteum from one side and to fasten it securely beneath the separated margin of the opposite side. This is to a certain extent a modification of a mode of treatment by flaps introduced by the late Mr. Davies-Colley. The measures which I usually adopt can be best illustrated by diagrams. Fig. 16 represents a cleft running through the whole of the hard and soft palate. A flap which is attached to the margin of the cleft is turned up from the bone of the hard palate and is dissected off the soft palate. Its extent must vary with the area to be closed. There is practically no limit to the amount of flap that can be obtained, since the whole of the muco-periosteum covering the under and outer surfaces of the edentulous alveolus may be included in it, and this is sufficient to fill any gap in the hard palate, however large (see Figs. 20, 21, 22, and 23). Great care must be taken not to tear away this flap from the margin of the cleft in the hard palate. The latter part of

FIG. 18.

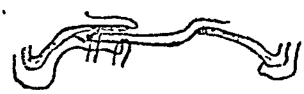
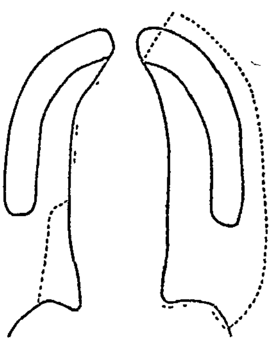
FIG. 19.



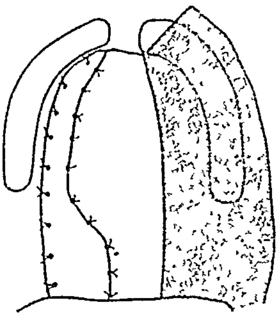
Showing the flap raised and fixed in position. It is a transverse section through Fig. 17.

FIG. 20.



This is a cleft of a breadth sufficient to require the employment of a flap from the entire alveolus. The dotted lines indicate the incisions, that to the left of the cleft being on the nasal surface of the palate, while that on the right is on the buccal aspect.

FIG. 21.



The flaps sutured in position. The shaded area represents the surface laid bare by the removal of the flap.

viz., the enlargement of the lymphatic tissues in the upper part of the pharynx—will disappear, and the so called adenoids will no longer exist, since I presume the term cannot reasonably be applied to the structure in its normal condition, but only in its chronically inflamed state. That this does take place I have satisfied myself with absolute certainty on very many occasions, and this has also been the experience of many others who have applied the principles involved in the treatment effectually. Authorities seem to form very different estimates as to the quantity and density of lymphatic tissue which the patient is justified in retaining without being dubbed "adenoids," and urgently calling for its removal. Specialisation in medicine and surgery tends often to extreme narrowness of vision on the part of the so called specialist. It attempts to appear to progress and it confuses issues of causation by using unmeaning terms which are apparently not capable of accurate definition. Words like "adenoids," and the equally indefinite one of "hyperplasia," instance products of these processes. They possess different meanings in the minds of different people and even under different conditions.

Not only does the enlargement of the lymphatic masses in the naso pharynx subside under this treatment, but there is also a corresponding improvement in all the conditions I have described as being consequent on imperfect oxygenation of the blood. This is now fully recognised by a large number of able and experienced medical men who apply in their practice the principles indicated in this and previous papers. Any person of average intelligence should be able to appreciate these views were it not that in many cases the medical creed of the individual and his interests coincide only too closely, his capacity to grasp general principles being in consequence unconsciously and involuntarily limited.

The only circumstances under which I can understand the surgeon being warranted in attacking the pharyngeal tonsil are (1) when the condition has been so thoroughly neglected that the child is unable to drive air through an undeveloped naso pharynx unless the enlarged pharyngeal tonsil is surgically removed; (2) when for some reason or other, such as considerable difficulty in forcing air through the nose, serious ear trouble, important school or other engagements, peculiar circumstances, &c., it is necessary or advisable by operative measures to shorten the duration of the treatment, and (3) when the child is too young to do what it is told. In private practice the first condition should not exist, and it only arises because absolutely no attention is paid to the manner in which a child performs by far its most important function—namely, respiration, by means of which the oxygen, the prime factor of life, is distributed to the several tissues in the body. Many inquiries are made as to the manner in which the intestines perform their functions, and if, because of an imperfect supply of oxygen and owing to the constant assumption of sedentary and resting habits, these viscera are not fit to carry out the work they should do in a healthy subject, they are stimulated in an unnatural manner by drugs. Too often one finds that the patient who exhibits no thoracic respiration whatever has the spine fixed in a position of extension by a steel support or by some form of brace, while at other times exercises are ordered which rapidly exhaust the child's imperfect capital of oxygen. This all results from an insufficient knowledge of the mechanics of the respiratory process, and especially of the important part which the spinal column takes in it. The physiologist has misled the profession chiefly by his attempts at illustrating the respiratory process by means of a mechanism in which the spinal column is represented as a rigid immoveable rod. As is too often the case, the generally received teaching is absolutely false, since the variations in the spinal column are much more conspicuous than those of the rest of the wall of the thorax. I would therefore urge that the mode in which the organism is supplied with oxygen should receive at least as much attention as the rate at which the sewage products are evacuated from the body. If the former is done, and done well, the various degrees of adenoids, the conditions on which they depend for their causation, the several varieties of resting deformities and many other states directly and indirectly due to imperfect aeration will disappear. Let medical men treat their patients in a common sense manner, regarding them simply as machines, recognising that they bear only a mechanical relationship to their surroundings and they will soon observe a rapid improvement in their physique. When difficulty is experienced in inducing the patient to pursue such respiratory exercises as increase the vital capacity it is well to place a trained nurse in charge, when progress is generally rapidly made even in very young children. I hope that we may soon have the advantage of hearing expressed fully the views of dental surgeons upon that portion of this question which interests them, especially as it is clear that their opinions and observations must be very valuable indeed.

The dental aspect of the case appeals to me most strongly for the reason that the observations of the dental surgeon are recorded indelibly in plaster casts. These are capable of the most accurate definition and measurement and do not depend mainly upon the statement of the observer which must vary of necessity with his education and interest. My dental friends have been of the greatest service in helping me to obtain accurate information as to the changes that ensue in the jaws and palate, not only from the absence of normal aeration, but also from the restoration of that function. I trust that my views and experience may be of some use to dental surgeons in the treatment of the deformities that they meet with so constantly in the present day and especially of superior protrusion.

When the septum between the naso pharynx and the mouth is incomplete the mechanical factor upon which the nasal cavities depend for their development is in abeyance, and therefore they do not increase proportionately in size. In consequence the sides of the alveolar arch become approximated, as do the edges of the cleft, and the portions of the roof on either side become more vertical and extensive. I will call particular attention to this, since it will be found that many surgeons use as an argument in favour of delaying the operation that the changes in the roof of the mouth which I have indicated take place in time and render surgical interference more simple at a later date. In other words the less developed the nose the more easy the operation for the closure of a deficiency in its floor. Since the calibre of the nasal cavities bears an inverse proportion to the height of the palate, and as the lower part of the nasal fossæ is that through which air is chiefly transmitted, this is especially encroached upon by any abnormal increase in the height of the palate. Being aware of the mechanics of the naso pharynx, it will be easy to recognise the immense importance of separating the mouth from the nose as early in life as possible so that the pressure exerted by the air as it passes through the former can be brought to bear upon the walls of the space and the nasal cavities and the adjacent bones influenced by normal developmental factors.

In order to recall to mind the practice followed by surgeons of the present day I will quote a few lines on the treatment of cleft palate from Treves's "System of Surgery," which is, I think, one of the most recent English text books: "In the infant the cleft is by almost all surgeons rightly deemed inoperable. In the child, after the age of two years the chief importance of the malformation is the defect of speech which is occasioned. It is well, therefore, to be prepared for the fact that the closure of the cleft in no way remedies the defect of articulation. Of prime importance is the question, At what age should the operation be performed? It may, I think, be laid down that whilst it is never wise to operate on a child under three years of age, the time of election is from this age up to six years." These definite statements which are picked out from the text, we may regard as representing generally accepted views and as open to our criticism. The author does not appear to adduce any argument in support of the first statement—viz., that surgeons are acting wisely in avoiding operations in infants, therefore, we may satisfy ourselves by merely asserting that, in our opinion, this statement is not borne out by our experience, but that the reverse is true. The second statement is, I fancy, partly correct. Some patients will, however, complain more of the discomfort which they experience through food getting into the nose than from the consciousness of the fact that their voice differs from the normal. The chief disadvantage of the deformity depends upon whether it is regarded from the point of view of physical discomfort to the sufferers or of depreciation of them in the opinion of their fellow creatures, since the peculiar intonation, *per se* causes no discomfort and is often not recognised by the speaker. Now as to the statement that "it is well further to be prepared for the fact that the closure of the cleft in no way remedies the defective articulation." This I am prepared to deny if the operation is performed during the period of growth. The reason that the any portion of the flap-covering in the cleft in the hard palate to give way, but occasionally the margins of the soft palate may come apart. To remedy this after an interval of two or three weeks a flap should be taken from the side of the hard and soft palate opposite to that utilised on the first occasion and be retained by the same method in the cleft, one of the methods indicated in Figs. 25, 26, 27, and 28 being employed. The area of the flap employed must necessarily vary with the size and form of the cleft and the thickness and vascularity of the part. By this means the sutured surfaces are exposed to a minimum of strain. To render this method of operating in the young infant possible it was necessary to devise an instrument for the purpose, since those in common use at the time were inefficient. The needle-holder and needles shown in Fig. 29 meet all possible requirements. The needles are made straight and full-curved, and they vary in size from three-eighths of an inch upwards. For pinning the flap the straight needles are best suited while the curved ones are more serviceable in the later stages of the operation. The sutures used are of the finest silk and are employed dry to facilitate threading. The gag which I employ is one that was made for me by Messrs Down Brothers some time ago It is perfectly self-retaining owing to the presence of small, sharp teeth, which bite into the gum behind the molars. It is depicted in Fig. 30 and is shown in position in Fig. 31. It is well to be provided with several sizes of this gag. The gag most generally used is too powerful for the infant only four weeks old. Messrs. Weiss made me a very useful pair of forceps which have terminal teeth and approximating serrated plates. (Fig. 32) By means of the teeth the flap can be held and with the plates the operator can grasp the needle firmly and readily and can draw it through the flap when necessary. Messrs. Down Brothers constructed lighter and shorter instruments which I have also found useful. (Figs. 33 and 33 A.) As a rule, the needle is taken up and drawn through the flap by the needle-holder.

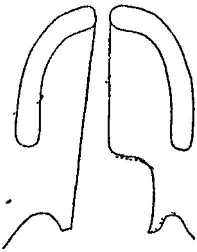
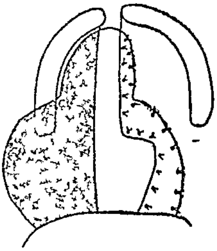
As I tapped a perfectly new source I was inundated with material, the mothers being delighted to have the deformity removed as early in life as possible. Owing to this circumstance I have possibly performed more operations for cleft palate for some time than any single surgeon has ever done or ever will do in the future. It now seems almost impossible to look back to the time when clefts in the palate in children of three years old and upwards were closed with large clumsy needles of various shapes attached to long handles and called cleft-palate needles. As soon as it is possible the respiratory capacity should be carefully attended to and all air should be driven habitually through the nose the operation can be done very well with a knife or by means of very sharp pointed scissors. In doing this the descending palatine vessels are exposed as they emerge in a loose periosteal sheath from a single foramen. These can be "cut long," and any hæmorrhage can be readily controlled by ligature, by torsion or by forcible compression.

FIG. 22.



This represents a common form of cleft in shape like a Queen Anne chair in profile. The dotted lines on the nasal aspect to the right of the cleft and on the buccal aspect to the left of the cleft indicate useful incisions.

FIG. 23.



The flap in Fig. 22 in position and sutured.

At this early period of life the vessels are very small and the amount of blood lost is always trifling. On no occasion have I ever felt the slightest anxiety on that account. This was certainly not my experience when operating on children over three years of age. Indeed, it was in a case of cleft palate apparently moribund from loss of blood that I first applied the method of intravenous injection of saline solution which has since been the means of saving so many lives not only from hæmorrhage but also from exhaustion, as in cases of intestinal obstruction, &c. The case was described in THE LANCET of Sept. 12th, 1891, p. 626, under the heading of "A Surgical Tribute to the late Dr. Wooldridge." There had been published in the Transactions of the Obstetrical Society of London for the year 1879 the report of an investigation on transfusion carried out at the request of that society by Professor Schäfer in which he asserted that the intravenous injection of saline solutions served no useful purpose whatever and insisted that it should not be employed. Needless to say the researches made by Dr. Wooldridge completely negatived the conclusion arrived at in the report. The following are Professor Schäfer's own words (page 333): "Solution of salt and any other watery fluid is without permanent benefit and should never be used for transfusion."

To close the cleft an incision is made along the opposite free margin of the cleft in the hard palate and the muco-periosteum is raised from the bone for about a quarter of an inch. The soft palate on the same side is pulled forward, being held in forceps, or a thread may be passed through its extremity. It is split in the same manner as is indicated in Fig. 24, none of it being removed. If more material is required a flap is cut from the posterior aspect of the soft palate so as to increase still further the area of the raw surfaces which can be brought into accurate apposition with the upper surface of the flap reflected from the opposite side. The reflected flap is first introduced between the separated edge of the muco-periosteum and the bony palate and its margin pinned at intervals by sutures. Then the edge of the flap of the soft palate is similarly attached to the outer limit of the raw surface on the back of the opposite margin by separate sutures. The free limit of the elevated border is attached securely to the raw surface of the reflected flap by sutures. In this manner two large raw surfaces well supplied with blood vessels are retained immoveably in accurate apposition and free from strain and are placed under the most favourable circumstances for immediate union. In many cases, especially in narrow clefts limited to the soft palate, I find that the old method of freshening of the edges of the divided palate, tension being removed from the line of suture by vertical incisions, gives excellent results. This is clearly of no use when the cleft is horseshoe shaped. It is very unusual for

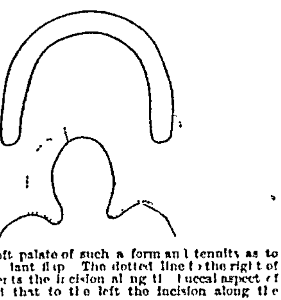
FIG. 27.



A cleft in the soft palate of such a form and tenuity as to require an abundant flap. The dotted line to the right of the cleft represents the incision along the buccal aspect of the palate and that to the left the incision along the pharyngeal aspect.

Having received information about the same time of several similar accidents, of which I need not give details, where women's and children's hair was set on fire by celluloid combs while they were seated, perhaps drying their hair, in front of ordinary fires, none of which cases fortunately proved so severe as that just reported, I requested the assistance of Professor Japp, professor of chemistry in the University of Aberdeen, as to the ignition point of articles sold as celluloid and generally as to what was known on the subject. This he most kindly gave me and to the following effect. His experiments were mostly made with pieces of combs worn by Dr. Beddie's patient and identical with that by which she had been injured. Professor Japp wrote as follows:—

> I have ascertained, as nearly as it can be done, the ignition temperatures of the two specimens of celluloid—light coloured and dark coloured—which you submitted to me for examination. I cannot detect any difference in their behaviour on heating, but they are both unduly sensitive to heat. On dropping small pieces into a test tube heated to a perfectly constant temperature of 270° F. they began to swell up and froth, and within one and a half minutes from the beginning of the experiment they suddenly decomposed with a puff of smoke leaving a charred residue. On one occasion I succeeded, by gradually raising the temperature, in inducing this sudden decomposition as low as 264° F., but this difference is very slight; moreover, in this way of performing the experiment much depends on the rate at which the temperature is raised; if this is done very slowly one may effect a slow decomposition, and the residue is not charred.
>
> The following data with regard to the action of heat on celluloid are taken from the "Journal of the Society of Chemical Industry," vol. x., p. 564. They will show you that this substance is expected to exhibit greater stability than the foregoing specimens: "At 194° F. it becomes very plastic, further heat softens it, and at a temperature of 285° F. it decomposes into pyroxyline and camphor aldehyde. At 383° F. the decomposition is instantaneous, the nitro cellulose inflames, and the camphor is vaporised." Your specimens therefore exhibit this sudden decomposition more than 100 degrees lower than properly manufactured celluloid.
>
> I thought I would examine at the same time a celluloid hair pin which I obtained from a member of my family. In appearance the celluloid was indistinguishable from your dark-coloured specimen, but it stood a constant temperature of 270° F. for 15 minutes without showing any change beyond slight swelling up and giving off a little camphor with a mere trace of nitrous fumes. There was no trace of the sudden decomposition which your specimens showed almost immediately under the same conditions.
>
> Of course, even the lowest of the ignition temperatures which I observed with your specimens is far above what would prevail at a distance of six feet from an ordinary fire. But it is a matter of common observation with unstable and explosive substances that they occasionally explode, or ignite—as it were, by mere chance and when they are not wanted to—under conditions that, when one is experimenting with the substances, would appear to ensure perfect safety. In the case of substances like celluloid this is readily explicable, as they are mixtures of variable composition, and they give way at the weakest point. A badly manufactured piece communicates its instability to the whole.

Professor Japp was further good enough to write to Professor C. V. Boys on the subject of ignition of celluloid. The only additional point in Professor Boys's reply is contained in the following remark: "The curious thing about the celluloid button smoulder (it is under the usual circumstances smoulder rather than burn) is that with all the smoke and fluster and stink there is nothing that cannot be put out by blowing sharply upon the place so as to cool it. The instinct, on the other hand, to squelch it by squeezing it all up in the surrounding material, is just the one thing to make it go all the more, as it is then made warmer, and what is more important the hot gases have no free egress, so they envelop the button and a kind of unstable state is engendered which results in a kind of deflagration or slow explosion, burning possibly severely the enveloping hand."

As Professor Japp's scientifically exact laboratory experiments left it open to be supposed that the conditions under which what is sold as celluloid would ignite, might, under ordinary circumstances, when it is exposed to radiant heat and surrounded by substances of varying conductivity, harmonise with both his results and the accidents reported, I performed, with the help of Dr. Fortescue, the following experiments in the rooms of the surgery department.

*Experiment 1. Heat in front of a bright fire.*—A thermometer surrounded on all sides with air and placed two feet in front of a well-burning fire showing both flames above and red incandescence below, reached a maximum temperature of 120° F. By stirring the fire or otherwise increasing the blaze the temperature could be raised a good deal higher.

*Experiment 2. Heat increases in the presence of an absorbing substance.*—If placed in the same position as in Experiment 1, with a backing of brown American cloth in contact with it behind, the thermometer registered 152° F.

*Experiment 3. Horse-hair further increases heat and affects celluloid.*—If similarly placed and backed with black horse-hair cloth the thermometer marked 171° F. A piece of the celluloid comb which burnt Dr. Beddie's patient, placed in contact with the horse-hair, swelled and became white and spongy at this temperature.

*Experiment 4. A steel pin further increases heat and ignites celluloid.*—A portion of the same comb, placed under conditions similar to Experiment 1 against the steel of a hat-pin which Dr. Beddie's patient was wearing when her accident occurred, the steel likewise touching the thermometer, ignited and left a black ash at the moment the thermometer registered 200° F.

*Experiment 5. Effect of wrapping celluloid in black hair.*—The thermometer and a third portion of the comb were enveloped in a small lock of the hair (black) of Dr. Beddie's patient and exposed as in Experiment 1. The celluloid burnt when the thermometer marked 180° F.

*Experiment 6. Variability of igniting point of celluloid.*—On repeating Experiment 5 a fourth piece of the same celluloid comb ignited only at 220° F.

*Experiment 7. Effect of wrapping celluloid in fair hair.*—The thermometer and a fifth portion of the comb were enveloped in a lock of a child's (fair) hair. The celluloid burnt at 167° F.

*Experiment 8. Control experiment to Experiment 7, with celluloid alone.*—A control experiment under exactly the same conditions as Experiment 7 gave 170° F. as the burning point of a sixth fragment of the comb taken from the spot adjoining that used in Experiment 7, when exposed naked, without being enveloped in the hair.

*Experiment 9. Control experiment with good celluloid.*—A piece of properly manufactured celluloid, exposed under identical conditions with Experiment 8 in order to control it, only became softened at 170° F.

The thermometrical temperatures in these experiments have only a relative, not an absolute, value.

### CONCLUSIONS.

1. It is evident that celluloid articles of uncertain composition and dangerously explosive quality are everywhere sold and are in constant use, and that the conditions under which they may ignite in varying circumstances cannot be fully inferred from experiments regarding their ignition point made in a physical laboratory.

2. Badly manufactured celluloid ignites at variable temperatures, too low for it to be safely used.

3. It also follows, I consider, that restrictions should be imposed upon the sale of all such articles which do not sustain, without ignition, a temperature equal to that sustained by well-manufactured celluloid.

4. It is worthy of consideration whether all celluloid articles of personal wear and such others as might give rise to fires ought not to be compelled to have the word "ignitible" conspicuously imprinted upon them.

5. If the suggestion of the writer in THE LANCET[1] to render celluloid incombustible by the addition of some chemical should be practicable it would be the best solution of the difficulty, and such an addition ought to be made compulsory by legislative enactment.

I owe my sincere thanks to Professor Japp for his advice and criticisms concerning his and my own experiments and to Professor Boys for permission to quote the sentences from his informal letter.

Aberdeen.

# A CASE OF HYDATID DISEASE OF THE GALL-BLADDER.

BY LAWRIE HUGH McGAVIN, F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE HOSPITAL FOR WOMEN, SOHO-SQUARE,
AND TO THE NORTH-WEST LONDON HOSPITAL; LATE
SURGICAL REGISTRAR OF GUY'S HOSPITAL.

THE following case of hydatid disease of the gall-bladder having recently come under my notice I have been tempted to record it as an example of what is, I think, generally acknowledged to be a distinctly rare condition.

The patient was a married woman, 32 years of age, who was transferred to my care in the Hospital for Women, Soho-square, by my colleague, Dr. James Oliver, with the following history. Until 14 years of age she had been perfectly healthy, but at the age of 16 years she suffered somewhat from anæmia (she stated that she had "inflammation of only Then by vocal exercises phonation must be made as perfect as it can be

---

[1] THE LANCET, March 26th, 1892, p 708.

3 *Harelip* —Many children with cleft palates are also afflicted with harelip Contrary to universal custom I leave the latter untouched till the fissure in the palate has been closed since it affords a larger aperture and renders the cleft very much more get at able and the operation correspondingly easier to perform perfectly and with a minimum of damage to the soft parts than it would be if the harelip was treated in the first instance I do not pretend to obtain the same results in the treatment of harelip as are apparently got by some surgeons, if one can place any reliance whatever upon the diagrams which they use to illustrate their methods of procedure These, I fancy, are purely imaginary, since they appear to be able to restore the imperfectly developed lip to its normal form and to its relationship to the lower lip My experience is that, excepting in slight cases, the upper lip always remains smaller than normal and disproportionate in size to the lower In some few cases I have obviated the relative loss by filling in this gap by a flap obtained from the lower lip, with which it remains continuous till it has united firmly to the upper I would point out also the advantage of passing all the sutures through the lip from within outwards, since by so doing the margins of the cleft can be brought into firm and accurate apposition and are enabled to control the hæmorrhage without scarring the skin surface, as is frequently done when the sutures pass through the skin in the usual manner

FIG 33

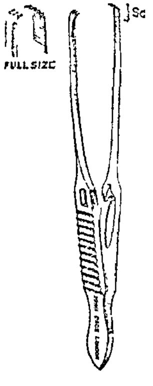


FIG 33 A

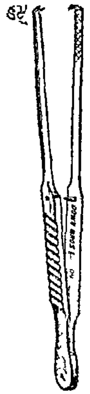
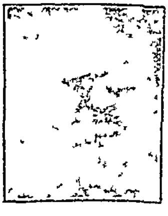


Forceps with terminal teeth for manipulating the flaps while the incisions are being made

FIG 34



Represents a case of double harelip with considerable forward displacement of the premaxilla

Besides, they can be left in much longer, as their presence causes no discomfort and retains the raw surfaces in accurate apposition The scarring of the lip was a more marked feature when the old fashioned harelip pins were employed

There is a form of cleft palate combined with double harelip in which the premaxilla is attached to the under surface of the septum of the nose immediately behind its tip (Fig 34) In such cases I have found that the most satisfactory procedure is to close one of the fissures in the lip in order to supply the premaxilla with blood vessels from a source other than the septum When this has been effected the premaxilla can be cut away from the septum, the mucous membrane covering it and the corresponding surfaces of the jaw can be removed, and the bone being trimmed and replaced can be wired securely in position The remaining fissure in the lip can then be closed, but by leaving it open till this period more room to work in is obtained and the details of the operation on the septum, &c, can be carried out with greater facility and accuracy

# BURNS FROM CELLULOID

By ALEXANDER OGSTON, LL.D GLASG, M D ABERD,
CONSULTING SURGEON TO THE ABERDEEN ROYAL INFIRMARY,
REGIUS PROFESSOR OF SURGERY IN THE UNIVERSITY
OF ABERDEEN

BURNS from celluloid seem to be by no means uncommon The *Weekly Scotsman* of Jan. 19th, 1901, page 3, mentions an accident of this nature in which a woman, "kneeling in front of, but by no means very near to, a clear red fire, and having an imitation tortoise shell comb in her hair on the top of her head, became conscious of a smell of burning and a very disagreeable vapour around her, and on putting up her hand found that her head was on fire She poured water over it and got it out, but not before a great deal of her hair was burnt There was no other light but the fire, and it was not a case of sparks The comb must have ignited of itself" The same paper mentions the case of a "girl at Peckham whose imitation combs caught fire exactly in the same way and who died in a London hospital 24 hours later from the injuries received", and also of a "married woman at Newport who only last week lost the sight of both her eyes from a similar accident" It concludes a short article on the subject thus "I may mention another fruitful source of danger—the celluloid collars which many children wear, and some adults too they are fearfully inflammable The hot ash from a cigarette, cigar, or pipe falling on them sets them in a blaze at once, and as they are tightly fastened round the throat it is almost impossible to remove them before serious injury has been inflicted A leading medical journal some time ago cited several accidents which had arisen from this cause"

Dr Irvine Fortescue, assistant professor of surgery, has collected for me the following references to celluloid burns which have appeared in the leading English medical journals during the past 10 years —

1 THE LANCET, March 26th, 1892, p 708 Experiments with articles made of celluloid Portions placed 18 inches in front of a fire swelled and gave off dense fumes at 110° C (230° F) Artificial ivory acted similarly at 145° C (261° F) The writer (anonymous) suggests that celluloid should be made non inflammable by the addition of some chemical

2 THE LANCET, May 15th, 1897, p 1386 A boy wearing a collar made of celluloid, tied with a string, having no knife to cut the string, attempted to remove the collar by burning the string The collar ignited and lighted drops of the composition fell on his clothing His throat and face were badly burned.

3 THE LANCET, May 22nd, 1897, p 1426 Artificial ivory horn &c, are nitro compounds and are almost explosive Accidents from this cause are increasing

4 THE LANCET May 29th, 1897, p 1481 Fires in Paris due to kinematograph films igniting

I have myself been made acquainted with several cases of what appeared to be the almost spontaneous ignition of celluloid hair combs the one which impressed me most, as having been attended with the severest results, being that of a patient of Dr L B Beddie of Fraserburgh who, when seated in a drawing room before a fire which, though burning well was not unusually strong, found her head enveloped in smoke and flame from the ignition of a comb amongst her hair and before the flames could be extinguished had a portion of her scalp destroyed over an area of, perhaps four by one and a half inches The burn was of the third degree, took many months to heal, and resulted in the total destruction of the hair over the injured area the second case, reported by Mr. J. Knowsley Thornton,[2] the symptoms of acute biliary colic were present; they recurred once and were then followed by jaundice and choluria. Here the gall-bladder contained a number of hydatids and much bile-stained fluid, the cystic duct being patent, and one other cyst was removed from the omentum. The third case is reported by Mr. Frederick Page,[3] the symptoms being chiefly vomiting and epigastric pain. A tumour was felt and on aspiration yielded perfectly colourless fluid. Cholecystotomy was performed and the organ was found to contain a single cyst without daughter cysts, the cystic duct being patent. Mr. A. W. Mayo Robson[4] mentions a case of hydatid disease simulating gall-stone attacks in which hydatids appear to have been discharged from the liver into the bile-ducts, infective cholangitis being the result. But here the disease appears to have originated in the liver. The same author draws attention to certain cases, all of which appear either to have originated in the liver or to have been complicated by communications between the liver and gall-bladder, leaving the original site of the disease in doubt.

With regard to the diagnosis of hydatid disease of the gall-bladder I am unaware of any case having as yet been diagnosed before operation. The difficulties in the way of making such a diagnosis are obvious and beyond the recognition of a tumour as being the gall-bladder in a state of distension (presuming always that no other swellings exist), I doubt if a definite diagnosis is possible. As to the treatment of such cases it must necessarily be considered from the special aspect of each individual case. In my own case cholecystectomy would have been clearly indicated (the cystic duct being no longer patent and the mucous membrane completely destroyed by pressure) even had the case not been considered one of malignant disease. The patient, I may say, has made an uneventful recovery. The specimen has been deposited in the Hunterian Museum, where it is at present the only one of its kind.

Montagu-street, W.

# TETANUS FOLLOWING REVACCINATION ON THE LEG;

## RECOVERY AFTER PROLONGED ADMINISTRATION OF CHLORAL HYDRATE.[1]

BY WILLIAM FINDLAY, M.D. GLASG.,
AND
JOHN WAINMAN FINDLAY, M.D. GLASG.,
ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY, AND ASSISTANT TO THE PROFESSOR OF MEDICINE, ST. MUNGO'S COLLEGE, GLASGOW.

THE patient, a female, aged 21 years, was revaccinated on March 8th, 1901. As she desired very particularly to use her arms in a fortnight's time she asked that the inoculation should be done on the leg. Accordingly a mark, a little over half a square inch in size, was made on the outer side of the right leg, about midway between the knee and the ankle. Calf lymph, as supplied by the Health Office of the City of Glasgow, was used, and more than the usual precautions were taken to prevent septic infection. The middle third of the leg was cleaned with turpentine and then with methylated spirits, after which the part was again rubbed over with a carbolic solution (1 in 40). The lancet used was always kept in a glass of carbolic solution. A large adhesive thick felt or bunion plaster was then applied around the vaccination mark and was kept in position by a strip of adhesive plaster, the object being to prevent any contact of stocking or clothes with the wound on the way from the surgery to her home until it was quite dry. The vaccination "took," constitutional and local symptoms were quite insignificant, and the patient was able throughout to do serious mental work and to go about as though nothing had happened.

On the 18th (10 days after inoculation of the vaccine) she attended a concert in a hall which is notorious for its draughts and she occupied a seat in a specially draughty place. While listening to the music she complained to her friends of the discomfort she was experiencing from the draught. On the 20th (12 days after inoculation) she first complained of pain in her back, felt out of sorts, and could not settle to work. On the 21st she remained in bed and was first seen by one of us. Her temperature was normal; the pulse was 80, small, of somewhat high tension, and regular, and over and above the pain in the back there was complaint of stiffness of the neck and the jaws. There was no sore-throat and no abnormality of the thoracic or abdominal organs was detected. Through some misapprehension the adhesive plaster had never been removed from the leg, and when crust and plaster were pulled off the vaccination mark did not look particularly healthy; it was covered by a greyish-coloured slough and there was a slight discharge of thin dirty yellow pus. There was, however, no surrounding inflammation of the skin and no enlargement or tenderness of the popliteal or femoral glands. A bread poultice was ordered and this at once converted the foul sore into a healthy, healing wound, which was afterwards dressed daily with moist boric lint. (We may as well state here and be done with it that in three weeks' time from the inoculation the vaccination sore was healed.) Under the impression that she was possibly suffering from a rheumatic affection of the muscles about the neck salicylate of soda (15 grains), four times daily, was prescribed.

On the morning of the 22nd her condition was much the same as on the previous night. As the day wore on, however, the jaws got stiffer and gradually closed till by the evening she could only open her mouth to about half its usual extent. There was no rigidity or spasm of the masseters or depressors of the jaw to be detected, and with a little trouble we could still assure ourselves that there was no sore-throat. There was no difficulty in swallowing. The head was very distinctly retracted, and though the patient could raise it off the pillow and make the chin touch the sternum, she complained much of stiffness and slightly of pain in the back of the neck. The muscles of the back of the neck, however, did not feel specially rigid. Slight tenseness of the muscles of the abdomen was felt, but there were no spasms of these muscles and no pain was complained of in them. No hysterical stigmata were present. The temperature was normal and the pulse was slow (68) and regular. On the morning of the 23rd the patient seemed much better, though she had not slept much during the night. She could open the jaws well and was quite happy about herself. As the bowels had not moved since the 20th, though cascara sagrada had been given on the 22nd, the same drug, in tabloid form, was again ordered, to be followed by an enema. In the evening the jaws could be less widely opened. Pain and, for the first time, twitching of the muscles of the abdomen in the region of the right groin were complained of, and also some stiffness in the right leg. The left knee-jerk was active, and on the right side it was markedly exaggerated, showing a tendency to clonus. There was no disturbance of sensation. The salicylate of soda was ordered to be stopped and chloral hydrate, in 20-grain doses, to be given every two or three hours till the spasm was relieved and sleep was induced

On the 24th it was ascertained that in spite of the administration of 60 grains of chloral hydrate the patient had had very little sleep during the night. In the morning the jaws could be opened sufficiently to give exit to the protruded tongue, but no more. The abdomen felt hard and board-like from constant tonic contraction of the muscles, and every now and then spasms or paroxysmal contractions occurred. The spasmodic contraction of the abdominal muscles was more marked over the right iliac fossa and caused considerable pain, which made her cry out. The spasm in the neck muscles was not constant, but was absent for short periods, and it varied in intensity from time to time. She could move the head backwards and forwards and from side to side within a limited range, but movement was carried out slowly with both pain and difficulty. There was some trouble in passing urine, but no actual retention. No chloral was given in the morning, and by the afternoon it was noticed that the patient had a fixed expression about the face, as if she had suddenly become aged. The eyes had a peeping look with small palpebral fissure, and could not be fully opened owing to the contraction of the orbiculares palpebrarum. The naso-labial and mouth angle folds were deeper than was normal, and the orbicularis oris and buccinators seemed and the womb"), and shortly afterwards, after suffering some difficulty and pain during micturition, she passed certain bodies resembling "grapes with the stalks removed," which her medical attendant told her must have come from the uterus. Of these bodies she passed one more at the age of 17 years and one at the age of 19 years. No examination appears to have been made of these. She had never been abroad, nor had her employment in any way been such as to have suggested the probability of echinococcus ingestion In April, 1898, she had a miscarriage and during the subsequent bandaging she noticed a mass in her abdomen which she showed to her medical attendant. It appears to have caused her no trouble until May, 1900, when she had a sudden attack of vomiting, accompanied by severe abdominal pain, and from this time the mass was tender on pressure and was accompanied by a feeling of nausea. She had no further vomiting, but in August the attacks of nausea became more frequent, lasting two or three days at a time. From this time the tumour began to increase in size and continued to grow, accompanied by increasing nausea and pain. These attacks bore no relation to her meals but appeared to be more usual towards evening. She had never suffered at any time from jaundice and her stools had always been normal in colour. She stated that she had lost weight considerably, but as no definite record was kept this was, I think, fallacious.

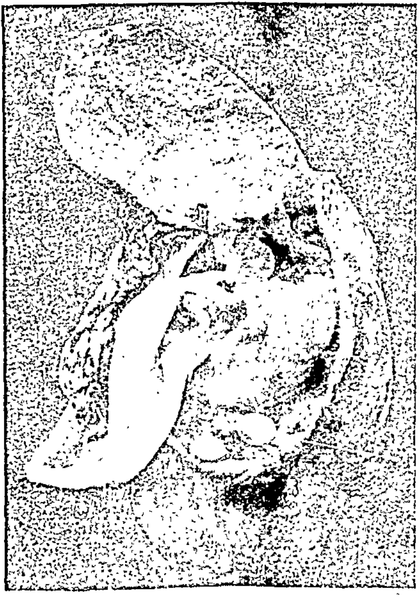
[4] Diseases of the Gall-bladder and Bile-ducts, pp. 42, 43.

[1] A paper read at a meeting of the Glasgow Eastern Medical Society, held on Feb. 5th, 1902.

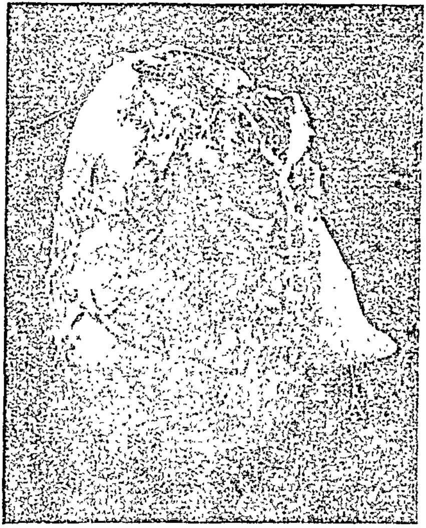
The case was seen by Dr. Oliver and myself in consultation on April 25th, 1901, when the following condition was found. Outwardly the abdomen was quite normal in appearance, no swelling being visible. On palpation the recti abdominis were felt to be separated by about an inch, and, lying slightly to the right of the middle line and about an inch above the umbilicus, was a hard, slightly lobulated, roundish mass which seemed to be rather flat than globular. It was freely moveable, especially laterally to the right, although it could be brought beyond the middle line to the left. In consistence it was hard, but not to a very marked degree; elasticity could not definitely be made out. On percussion it was dull and there was impaired resonance between it and the liver which was not enlarged. On pressing the tumour the patient complained of nausea, and on increasing the pressure of some pain in the epigastrium. As far as could be judged the tumour measured about three inches each way and was not apparently connected with the liver. In the absence of jaundice, colic, and clay-coloured stools, and from the very free mobility of the tumour, a diagnosis of carcinoma of the omentum was made, and I advised an exploratory laparotomy which was undertaken on May 2nd.

FIG. 1.



Front view. A, Hydatid membrane. B, Daughter cysts.

FIG. 2.



Back view. A, Hydatid membrane. B, Obliterated cystic duct.

On opening the abdomen in the linea alba I found a large whitish mass, measuring about three inches by five, having several flat prominences on its surface, of rather hard consistence suggesting nodules of growth, in the situation of the gall-bladder To this mass the great omentum was adherent in front, the edge of the liver was spread out over it above, and the transverse colon was in a similar condition below. The tumour was found to be the gall-bladder itself, and the position of it, so near the middle line, was accounted for by the fact that the liver was much more moveable than is usual, although the other viscera showed no marked degree of enteroptosis. Under the impression that I had to deal with a primary carcinoma of the gall-bladder I freed the organ without much difficulty, ligatured and divided the cystic duct (the lumen of which was then seen to be completely obliterated), and removed the gall-bladder. On opening it no fluid exuded, but it was found to be lined by a thick blanket of hydatid membrane unstained by bile pigment and which peeled away with extreme ease, the cavity of the cyst being occupied by numerous daughter cysts and gelatinous semi-translucent material. I then examined the other viscera for indication of more cysts, but I was unable to find any tumour or enlargement which might point to such, and, although time may prove to the contrary, I am strongly of opinion that in this case the gall-bladder alone was affected.

The rarity of hydatid disease affecting the gall-bladder, either solely or in conjunction with other organs, may be judged of from the small number of cases at present recorded I have been unable to find more than three cases recorded in the last 20 years. The first is that mentioned by Dr. Bowman,[1] in which the patient died during aspiration of a hydatid cyst of the lung. The gall-bladder was found post mortem to be distended by a single cyst of the size of a fœtal head containing one daughter cyst. There had been no signs of jaundice nor was pain at any time present. In given to the fact, as set down by Gowers, that "there is an absence of rigidity in the neck in hysteria,"[2] and Gowers's most sound and excellent advice, "that the symptoms of tetanus coming on after an injury or exposure to cold must not be treated lightly because they occur in a hysterical person or follow fear of the disease,"[3] was not at first sufficiently acted on. Though not hysterical our patient was distinctly neurotic and both knew about and had an awful fear of "lockjaw."

---

[1] THE LANCET, April 8th, 1876, p. 532.

We were loth, too, as is not surprising, to admit that the inoculation for vaccinia had at the same time sown the seeds of tetanus. Neither of us had ever heard of such a thing, yet we have been able to find references to 10 cases, where tetanus has occured after vaccination. Six, and perhaps seven, of these[4] are reported from America and two from the West Indies,[5] where tetanus itself is very common, but, unfortunately, we have not access to any of the journals containing the records of them. We learn, however, from the title of one paper that the patient was cured by large doses of opium; and from epitomes in THE LANCET and the *British Medical Journal* we get a very fair idea of the course of events in two fatal cases. A single and fatal instance of this accident is reported in Great Britain.[6]

In a case related by Toms[7] "tetanus occurred 24 days after vaccination in a weakly girl, aged five and a half years. Bovine virus was used with all possible antiseptic precautions. On the eighteenth day the child was ill, the temperature was 100·5° F., and the ulcer at the site of the vaccination was deep, slightly indurated, and discharging a sanious pus. These appearances improved under treatment and six days later the child had an aphthous stomatitis, and now for the first time, while the mouth was being examined, some trismus was noted. The muscular rigidity spread, opisthotonos developed, and the child died from œdema of the lungs 35 days after the vaccination. At the time of death the ulcer on the arm appeared to be healthy. Against the theory that the tetanus was due to vaccination are (1) the presence of the sore mouth; (2) the length of the incubation period if counted from the vaccination; and, most important, (3) the inability to cultivate the tetanus bacillus from the wound of the arm. The possible sources of infection of the arm were (1) the vaseline, (2) the sponge, and (3) the unsterilised dressings used by the patient's friends," but all these may perhaps be ignored in view of the bacteriologist's finding that the arm was not infected with tetanus bacilli, though it must be confessed that this finding loses much of its weight when we consider how very, very difficult it is to cultivate tetanus bacilli from wounds. The interval between the vaccination and the onset of trismus is somewhat over the average, but by no means too long for the incubation period of tetanus.

In another case investigated by the Royal Commission on Vaccination,[8] and published in their reports, "a female child, aged two months, developed trismus on the twenty-third day after vaccination. The child's arm did well up to the ninth day, when it became inflamed. Suppuration but no erysipelas set in on the fourteenth day. The child died with opisthotonos and interference with respiration on the twenty-sixth day. The reporter acquits the lymph used and the operation of being the cause of tetanus which is most unusual after vaccination. This child was vaccinated from the arm of a female infant, aged five months, and at the same time and with the same 'lymph' six other children were vaccinated, and none of them developed tetanus or sore arms. But tetanus may follow very slight injuries, and it is regarded as noteworthy that 28 days after the death of the above child another infant, aged 10 days, at a house half a mile off, died from tetanus supervening on an unhealed umbilicus."

In yet another case[9] "the patient was a healthy man, aged 40. Some days after the operation, which was performed about the middle of January last, he exposed himself to severe cold, and the arm became much swollen and the integument around the scab inflamed. No other lesion could be detected anywhere in the body. On Feb. 7th he noticed a little stiffness of the jaw and there was sligh opisthotonos, accompanied on the following day by profus perspirations and muscular spasms of the lower extremities. These symptoms increased in severity till the 13th, on the evening of which day death took place, the pulse at noon having been 120, the respiration 44, and the temperature 102·0°. Treatment throughout was by chloral hydrate and kalium bromide. Constipation was persistent during the entire illness. Dr. Berkeley acquits the virus of any share in producing the tetanus."

In our patient the first tetanic symptoms appeared exactly 12 days after the vaccination and two days after exposure to a draught. "The interval between the infliction of the wound and the appearance of the first symptoms of tetanus is usually from five to 14 days."[10] "Idiopathic tetanus usually follows exposure to cold, and when due to a single exposure, so that the interval could be ascertained, it has rarely exceeded two days and has frequently been only a few hours In many cases classed as traumatic tetanus there has been an exposure to cold after the receipt of the wound."[11] Now, considered from the point of view of length of incubation period we would be at a loss whether to ascribe the tetanic infection to the exposure to cold on the one hand or to the vaccination on the other, for both satisfy this criterion, were it not for the now generally accepted idea that all cases of tetanus are traumatic, and the further dictum of Gowers that "cases in which tetanus is apparently excited by cold in a person who has had a trifling injury, perhaps some time before, must be included for scientific purposes in the traumatic variety."[12] "The influence of cold has been thought to aid the occurrence of pu jaws well neonatal tetanus,"[13] but on the whole it seems mor ls had not ance with modern thought to regard "the exposu had been somehow or other predisposing the nervous syste was again from a minute dose of the tetanic poison."[14] vening the could not have been a large dose introduced in or the first amply proved by the mildness of the sympt n the region must conclude that the extra irritation in o some stiff- exposure to cold simply played the part of fir active, and already laid, just as Verneuil has noted that ed, showing ference with a wound may apparently excite t urbance of as bearing out the same idea is the case record ered to be "An injured toe had become gangrenous an es, to be tated. Trismus, absent before, was present a was relieved hour afterwards, and the patient averred that th operation distinctly made his jaw muscles c spite of the the amputation was being performed."[15] In B the patient there was also exposure to severe cold in the int ht. In the the vaccination and the development of tetanic ntly to give

The incubation period in our case was short The abdomen in one and by 11 in the other—than in two of ontraction of tioned above, and there was no abrasion, ulcera paroxysmal of cutaneous or mucous surfaces to interfere with on of the tions, as in the case reported by Toms. In all the he right cases, however, the duration of incubation if cou h made the time of the vaccination is well within the limits s not month—as set down by Gowers.[16] ed in

Now, granted that the poison of tetanus was intro head by the process of vaccination, we have the further que n a to answer—Whence came the poison? We do not see ith the lymph can be blamed, for, though drawn from ng agricultural source, the calf, which at once suggests man and dung heaps, several people were inoculated from t same tube, and this one patient alone developed tetanu Further, the probability is that had the lymph been th infective agent the whole output of a certain date wou felt tense. The abdominal muscles were still hard and board-like and paroxysmal spasms were occurring in the right iliac fossa. There were pain and stiffness in the back, and at times we thought that we could make out slight arching of the same. The head was distinctly retracted, and only with great difficulty and some pain could the chin be made to come near, but not to touch, the sternum. The extensor muscles of the neck were very hard and tense and, for the first time since the illness began, the masseter muscles were felt to stand out as stout bands. The legs were kept fully extended, and the feet were so strongly flexed as almost to continue the straight line of the legs. By gentle movement, however, after some little time this tonic spasm of the calf muscles could be overcome, and the feet could be brought forward almost to a right angle with the legs, but they would come no further. The patient distinctly objected to have her knee and hip-joints flexed and she could not sit up in bed. She had had 20 grains of chloral hydrate twice during the early part of the afternoon.

Up to this point, though tetanus had never been absent from our minds, it had seemed to us that all the symptoms could be explained by a diagnosis of hysteria; and the varying degree of the muscular rigidity—the malady appearing at one time to be progressing and at another to be receding—and the fact that such rigidity by gentle manipulation could to a great extent be overcome, coupled with the distinctly neurotic character of the patient, in spite of the absence of definite hysterical stigmata, seemed to lead in this direction But now we could no longer avoid making the diagnosis of tetanus, cerebro-spinal meningitis being excluded by the absence of fever, headache, vomiting, &c. In the evening Professor T. K. Monro saw the case in consultation and agreed with us that the malady was tetanus. It was arranged to give a further dose of purgative medicine (half an ounce of castor oil) thoroughly to clear the bowel and to continue the chloral hydrate in somewhat larger doses—from 20 to 30 grains every four hours. In view of the gravity of the disease, however, it was decided to obtain a surgical opinion to consult as to the advisability of operative interference. Professor Monro made an ophthalmoscopic examination and found the fundi normal Professor Sir Hector Cameron saw the case on the evening of the 25th, when the state of the patient was somewhat better than it had been on the previous day owing to two and a half drachms of chloral having been given during the last 24 hours. Still, all the facts which we have mentioned were present. Sir Hector Cameron agreed with the diagnosis of tetanus, but did not think that it was either necessary or desirable to excise the vaccination wound or yet to give tetanus antitoxin. He advised that the chloral be continued and even pushed, and, drawing from his great store of clinical experience, confidently asserted that the patient would ultimately get well.

From the 25th to the 26th the patient had had 240 grains of chloral during the 24 hours and by the 27th 180 grains more had been given. She was under the influence of the drug and was very silly and stupid—like a half-drunken person The eyes, however, were more widely opened, there was an absence of the ominous lines about the nose and mouth, and the slight sardonic grin was no longer perceptible. She could nod her head There was no spasm in the abdominal muscles, and the legs, in place of being extended as formerly, were now drawn up in bed. The only drawback to her splendid feeling of *bien-être* was that retention of urine had occurred. A catheter was passed at night. The improvement still continued and on the 29th the mouth could be more widely opened. During the last 48 hours 120 grains of chloral had been sufficient to allay any tendency to spasm. The catheter was passed twice during this and the preceding day. The temperature, which had previously always been normal, was 99 0° F. in the morning and 99 6° at night. On the 30th she passed urine herself, but the calls to do so became very frequent, and there was stinging pain at the end of each act of micturition. The urine was faintly alkaline and contained a slight sediment of pus. The temperature was 99 8° in the morning and 100 6° at night.

From this point onward to the end of April there was slight fever of an intermittent character, the temperature being off and on about normal in the morning and never higher than 101° at night The abnormal temperature coincided with the appearance of the cystitis, which persisted—as shown by pus in the urine—well on till the end of July. The bladder inflammation, due, no doubt, to the catheterisation, was treated all along with salol and urotropine, but chiefly the latter, which, on the whole, acted most beneficially. The chloral, in 15-grain doses, was continued at about the rate of five grains every hour, the patient calling for it as she was in dread of the spasms returning with their old force During the next three days advantage was taken of this improvement to wean her from the chloral and to substitute bromide of potassium, but the spasms in the abdomen and the legs returned necessitating a re-administration of the drug. From April 6th to the 22nd the spasms were kept under by the continued administration of the chloral day and night. So long as the patient was under the influence of the drug the spasms in the legs, the abdomen, and the back were fairly quiet and the rigidity of the muscles of the face and neck was well relaxed. Though dosed with the drug she lay in constant terror of the bed or herself being suddenly touched or jerked lest the old twitchings should come back. If anyone incautiously entered the room or walked roughly across the floor the spasms occurred. During this period she took plenty of nourishment of an entirely "sloppy" character as she was unable to chew owing to the rigidity of the jaws. By this date (April 22nd) she had consumed in all seven ounces three drachms and 10 grains of chloral. During the next fortnight the chloral was gradually lessened—exactly an ounce was given—until it was stopped altogether, and bromide of potassium in 15-grain doses four times daily was again substituted for a week, after which she was put on iron. Thus during her entire illness she took a little over eight ounces of chloral, or, to be particular, exactly eight ounces and three drachms, plus 10 grains, and never at any time was there the least sign of cardiac failure.

Towards the end of the first week in May, a day or two after the chloral was withheld, the nurse began to encourage the patient to sit up in bed, and later to get out of bed, but it was slow work, as the spasms threatened to return on the least exertion, and her extremely weak and nervous condition seemed, through terror, to anticipate, if not actually to make, them The knees and hips remained extended and for some time she could not sit down in a chair properly, but had to be propped up like a stiffened lay figure; and later, when she tried to walk, even though supported on each side, she could not lift or flex her limbs. In the legs the spasm was last to leave the flexors of the ankles; she could not set her feet down flat on the ground and walked for a period on her toes Perhaps fear of the spasms returning had something to do with her extreme helplessness and slow recovery. By perseverance, however, she gradually gained confidence and power, and towards the end of the month was walking with the assistance of the nurse's arm and a stick, though still holding her neck and back very stiffly. The trismus also remained to a slight extent and was the last of the rigidities to disappear. Solid food could now be taken in place of the finely-chopped meats required in the earlier part of the month. She was also regaining her natural sleep at night which was uncertain after the loss of the chloral. Early in June she went to the coast, where she was golfing by the end of the month and needless to say, free from all tetanic symptoms. It should have been mentioned that the muscles of the arms were never at any time affected and constipation was a marked feature throughout the entire illness.

## CONSIDERATIONS AND CONCLUSIONS.

In spite of the fact that we have no bacteriological evidence to offer, it cannot be doubted that the above was a true, though by no means a classical, case of tetanus. Further, as already mentioned, the patient was seen by Professor Sir Hector C Cameron and Professor T K Monro, and both concurred in this diagnosis. That we were not dealing with a simple rheumatism occasioned by the draught in which the patient sat two days before symptoms showed themselves was made evident by the stiffness of the neck being quickly followed by rigidity in the muscles of the jaw, and this at once aroused our suspicions These suspicions, however, we must confess, were somewhat too easily allayed by thinking that we had to deal with an extremely rare manifestation—tetanoid spasm, of that perennial pitfall and simulator of disease termed "hysteria" The trismus, however, was not sudden in onset and never became absolute, as happens in hysteria; still the variation in the amount of the trismus seemed to point to functional rather than to organic disease. Due prominence was not at first animals with samples of the different lymphs used." We do not know what authority the committee has for saying that if the virus had been contaminated tetanus would have ensued within nine days after vaccination. The authorities whom we have consulted do not give such a limited incubation period for tetanus. We believe that the lymph used by us was as free from tetanic infection as was that employed by the Camdenites, but our faith in our explanation by skin infection at the time of the vaccination remains unshaken. "In every instance it was found that vaccination had been performed in a correct and cleanly manner." But this has been said about all the cases of tetanus supervening on vaccination that we have read of and might be also truthfully said about our own case. "The committee thinks that the tetanus cases in Camden are to be explained by atmospheric and telluric conditions. There had been a long period of dry weather, with high winds, so that tetanus germs, which have their normal habitat in the earth, dust, dirt of stables, &c., were constantly distributed in the atmosphere. One case of tetanus occurred from gunshot wound during the same period in a boy who had not been vaccinated—a fact which the committee regard as proving that the tetanus germs were in the atmosphere." Now, in all seriousness we would ask, Is it sound reasoning to conclude that because one of the many injured and wounded persons developed tetanus during the same period that several cases of tetanus were occurring after vaccination, that the tetanus germs must have been in the air? Of course, the tetanus germs were in the air—they are always there more or less; but is not the logical conclusion to be derived from these facts what we have already stated—viz., that the vaccination wound offers special facilities for growth to the tetanus bacillus? If atmospheric and telluric conditions alone were to blame vaccination would not have claimed cases while injuries claimed but one case. "In all the cases it was found on careful examination that the wound had been exposed by the scab being knocked off or removed or the arm had been injured and infection resulted; frequently children scratched the vaccinated area with their dirty fingers and nails and thus infected the wound. It is given as the unanimous opinion of the Board of Health, as well as of its committee of experts, that tetanus or any other infection can never occur if the vaccination is properly protected from contact with the atmosphere or with soiled clothing, bandages, &c." In our case, as already mentioned, the scab was not removed till the symptoms of tetanus developed, and even had our patient been in possession of dirty fingers and nails she could not have scratched the wound on account of the covering that was over it. Proper protection after vaccination is not everything, and in all humility we would direct the attention of the Camden Health Board to the skin of its patients as the not improbable source of the infection.

# NOTES OF 15 CASES OF OPERATION FOR INTERNAL DERANGEMENT OF THE KNEE-JOINT.

BY J. M. COTTERILL, F.R.C.S. EDIN.,
SURGEON TO THE EDINBURGH ROYAL INFIRMARY; LECTURER ON CLINICAL SURGERY IN THE EDINBURGH SCHOOL OF MEDICINE.

JUDGING from the views expressed in various text-books and recent papers on the above condition there still seems to be a considerable diversity of opinion with regard to many points in the etiology, pathology, and treatment of so-called dislocation of the semilunar cartilage. It may not be inopportune, therefore, to add the experience gathered from 15 cases of operation for this injury, as well as impressions formed from the observation of a large number of cases in which operation was not considered necessary.

The few points which I propose to discuss naturally fall under the following heads: (1) etiology; (2) pathology; (3) symptoms and diagnosis; and (4) treatment.

## ETIOLOGY.

Most writers are fairly agreed on this point. The accident usually happens when the knee is partly flexed by a sudden external twist of the tibia on the femur, or, perhaps, more strictly speaking, an internal twist of the femur on the tibia. Such a thing may happen when a person steps out of a moving conveyance at too great an angle to the line of its movement, when he rises suddenly from the kneeling position, or in the course of football or similar games. I have known the internal cartilage to be displaced in three cases by a boy falling on the outer aspect of the patient's extended leg in a "maul" at football, and another case was caused by a vigorous kick at football missing the ball. I have not met with a case where a direct blow applied to the cartilage was the cause of its displacement, but I have known an accident of this kind to account for the separation of a chip of the bone (the tibia) with articular cartilage attached, this condition being found on opening the joint. As the cartilage recedes considerably into the joint on flexion and is so well protected by the adjacent margins of the tibia and femur in extension this cause for dislocation must be very rare, though it is said to occur. There can be no doubt that, as Mr. Annandale noted some time ago, miners and others who habitually kneel at their work are particularly prone to "derangement" of the knee. I have seen several cases in such people. Chronic synovitis is also recognised as a predisposing cause. It is a matter of common experience in cases where the cartilage has been previously dislocated and where satisfactory new adhesions have not formed, that the least twist of the knee, a slight tap on the inner side of the foot, and similar trivial causes will readily reproduce the displacement.

## PATHOLOGY.

With regard to the relative frequency with which the internal or external cartilage is affected, most writers are now agreed that the former is very much more commonly at fault than the latter. I do not know whether Mr. R. J. Godlee still adheres to the contrary opinion, but this view—an incorrect one, as I venture to believe—is still held by some authorities, and appears, for instance, in the last edition of Da Costa's "Modern Surgery." My own experience coincides with that of Mr. Annandale, Mr. A. E. J. Barker, and others. Out of the 15 cases operated upon only one has been external, and I have only seen two other "external" cases in some 50 cases observed but not operated upon. In every one of the 15 operation cases the displacement of the cartilage (or of part of it) was inwards towards the centre of the joint, and while now and then one sees a case of external or marginal displacement I believe the condition to be quite exceptional.

Cases have frequently been noted in which there was tearing of the cartilage. Mr. Barker,[1] in an interesting paper, describes various kinds of longitudinal splitting which may take place. The accompanying illustration (Fig. 1) is an excellent example of what he terms "central splitting," the cartilage being split from end to end, the separated strip of the meniscus having found its way into the middle of the joint and lying against the crucial ligament.

Separation of the anterior attachment of the cartilage to the tibia is of common occurrence. I have met with it in several cases. Mr. Barker states that in none of his cases was the cartilage torn across at any point between its two ends. Strangely enough I have met with this condition in almost half of my operations, and so common a circumstance does it thus appear to me to be that I think that the term "dislocation of the semilunar cartilage" is very often an incorrect one, and prefer Hey's old name of "internal derangement of the knee-joint," which, if somewhat vague, is at least not absolutely misleading. Out of my 15 operation cases six have presented a distinct transverse tear through the edge of the meniscus, the torn fragment projecting into the joint and causing the characteristic locking, while the greater part of the cartilage remained in most cases fixed in its normal position. (*Vide* Figs. 2, 3, 4, and 5.) Fig. 6 represents the only case of external cartilage removed, and here there seems to have been some longitudinal splitting, causing thinning of the meniscus towards its middle. In one old-standing case the cartilage was found to be greatly thickened; in another the "ligamentum alare" and "infra-patellar pad of fat" were found to be much thickened and had to be removed in part along with the torn cartilage.

## SYMPTOMS AND DIAGNOSIS.

The essential point in diagnosis is the inability *fully* to extend the knee. It is often stated that the joint is locked and that movements not only of extension but of flexion are impossible. Now, while a patient instinctively holds any have been contaminated, and a regular epidemic would have resulted, such as occurred in Italy and more recently in the City of St. Louis as the result of using diphtheria antitoxin.[17] It is important, too, in this connexion, to note that in the case examined by the Royal Commission on Vaccination, human lymph was used, and only one child out of the seven vaccinated from the same source and in the same manner developed tetanus. No more can we blame the lancet or the hands of the operator, for at that particular time (in the spring of 1901) medical men were doing little else but revaccinating, and yet out of the large number vaccinated on that particular day only this one patient developed tetanus.

---

[1] THE LANCET, Jan. 4th, 1902, p. 7.

We must conclude, then, that the source of the infection was in the patient's own skin, and it is to be remembered that the site of the inoculation was the leg, though in the three other cases referred to the arm was chosen. According to Thamhayn the order of frequency with which the several parts have been the seat of the wound that caused tetanus is (1) the hand, (2) the leg, (3) the foot, (4) the head and neck, and (5) the arm and trunk.[18] Of the many patients whom we vaccinated in this case alone did we do so on the leg, though we have seen it stated with authority that such is commonly practised on the infants of Canada, is the custom in Spain, and is unattended by danger.[19] But babies differ very materially from adults, and it is superfluous to point out how much nearer in the latter the leg than the arm, say, is to the great source of infection, viz., the earth. Moreover, it is important in this relation to remark that our patient conformed to the prevalent custom of wearing a long dress, and it seems hard to understand how skirts trailing along our city streets can fail to sweep up material, composed of finely pulverised earth, horse-dung, &c., and most likely containing tetanus bacilli and spores. The constant to-and-fro flap-flapping of the dress must cause the stockings very quickly to become seriously soiled with infective material, and in the case of women where wide-meshed stockings alone afford covering for the nether limbs below the knee there is no difficulty in following the infective agent through the stockings on to the legs themselves. It seems to us that, let a woman be ever so cleanly in her habits, perform ablutions as often as she likes, and change her garments as frequently as she pleases, she has only to walk a few yards—if she trails her dress—to furnish drachms oriologist with more than food for reflection.

Still, all tl iseptic measures employed, though considerable, Sir Hector (arse quite inadequate to destroy any spores of the did not thicillus lodged about the glands or the pits of the excise the ɔd, a few incantations would have been as effectoxin. We regret now that of being extenp the vaccination mark at the beginning and The only drawin sorry that through a misapprehension our that retentionerted the meant-to-be-temporary protection passed at niment covering, for the somewhat impervious on the 29thay have helped to produce those anaerobic During the; so necessary for the development of the tetanus sufficient Moreover, this sealing-up of the wound has was pasadvantage that it quite puts out of court any possi- The t of infection of the wound subsequently to the normanation. Further, it is important to note that in the On t'e fatal cases which we have quoted all the patients had so by sore arms, two of the arms being described as suppurat- end;. In our own case, also, the vaccination mark, though alkjt surrounded by induration and inflammation and though pe,ot associated with enlargement of glands, did not look particularly healthy, still that there was nothing much amiss s was amply proved by the absence of abnormal temperature, and the fact of a single poultice at once converting it into a healthy healing wound. "Kitasato now holds that in the natural infection in man, along with tetanus spores, the presence of foreign material or of other bacteria is necessary. Spores alone or tetanus bacilli without spores die in the tissues, and tetanus does not result."[20] Thus we see how "bad arms" may help in the development of tetanus; nevertheless, it is perhaps not entirely a question of the successful or non-successful use of antiseptics, and it is quite in harmony with Kitasato's teaching to believe that the vaccine virus itself and the consequences which it produces are quite capable of injuring the tissues to such a degree that the tetanus spores or bacilli may become pathogenic without the presence of any streptococci or staphylococci to aid and abet them.

This case was treated throughout by chloral hydrate, eight ounces three drachms and 10 grains being administered over a period of 44 days. No mild or heroic surgical measures were carried out and no antitoxin, as already mentioned, was employed. Had the tetanus antitoxin been used this case might have gone to swell the badly needed good results after such treatment. Encouraged by the confident prognosis of Professor Sir Hector Cameron, which was endorsed by Professor Monro, we waited (till not only our own patience but that of the patient's friends also was well-nigh exhausted) for the elaboration of a natural antitoxin by the patient's own tissues. That this consummation took a very long time we must confess, and it is possible that a resort to the use of animal antitoxin might have considerably expedited matters, though the ultimate result left nothing to be desired.

It may be asked what good end can possibly be served by reporting a case of this sort, so we hasten to make answer that we feel that it is only our duty to our medical brethren to do so; and if the perusal of this communication impresses the reader as we have been impressed, more especially since we began to study the literature of vaccination, with the great necessity for the employment of adequate antiseptic precautions when performing this most trivial of operations, the great cause of vaccination will be considerably helped thereby. It is more than doubtful whether many of us use an antiseptic otherwise than as a fetich. What are adequate antiseptic precautions? Can the skin be rendered aseptic or safe by scrubbing for a few minutes with disinfectants? Most surgeons, we believe, would give a very decided negative to the latter question and yet vaccination is riskier in some ways than a clean cutting operation. We are disappointed on reading over the third schedule of the Vaccination Order of Oct. 18th, 1898, issued by the Local Government Board, England, to find that though considerable space is devoted to the sterilisation of instruments, and the care and use of lymph, there is nothing more definite as regards the preparation of the skin than, "Vaccination should at every stage be carried out with aseptic precautions, and these should include: First, the cleansing of the surface of the skin before vaccination."[21] The neglect of the skin and idolatry of sterilised instruments are reflected likewise in the advertisement columns of the medical journals where instrument-makers are seen to vie with one another as to who shall produce the daintiest and most easily sterilisable outfit.

The accident in our case, fortunately so very rare, could hardly, we think, have been foreseen, and possibly could only have been prevented by adopting the same elaborate measures (extending over days) to render the skin aseptic which the surgeon employs before performing a major operation.

## ADDENDUM.

Since the above conclusions were formed and set down it has come to our notice that some cases of tetanus (number not stated) have occurred after vaccination in Camden, New Jersey, and we also learn that a committee has inquired into and reported on the matter.[22] We have tried to apply the findings of this committee of experts to our own case, and though we recognise that any opinion coming with such high authority cannot be treated lightly we see no reason to amend our conclusions in the slightest. "In every case acute tetanus occurred in from three to four weeks after vaccination, whereas if the virus had been contaminated tetanus would have ensued within nine days after vaccination. A further proof of the purity of the virus is afforded by the negative results obtained from inoculation experiments on is dealt with as follows: 1. If the cartilage is found entirely, or to a large extent, separated, or if much thickened or altered, excise the whole of it. 2. If the cartilage is separated from its anterior insertion into the tibia and curled into the joint, cut off the anterior part of the cartilage as far back as the internal lateral ligament. 3 If the cartilage is much torn or frayed in front carry out the same procedure. 4. If there is a torn tag or strip of the free edge of the meniscus projecting into the joint, while the main part of the cartilage is in place, cut off the tag or strip and leave the uninjured part 5 Under no circumstances is stitching of the cartilage, or part of it, into place advisable. More might be said for this plan if the injury were quite recent and the torn surfaces fresh. It is true that several successful cases of stitching have been reported, but there are others in which stitching has failed and the cartilage has had to be removed at a second operation. Removal of the cartilage (or of a large part of it, usually the anterior half) is such a satisfactory proceeding—every one of my 15 cases having returned to active exercise, some even to football, &c.—that there seems no argument against excision in suitable cases.

Drainage of the joint after operation is not only unnecessary, but is dangerous. No fingers or strong lotions should be put into the joint; asepsis must be beyond all question. In two weeks splints should be taken off and the patient should be encouraged to move the joint a little in bed. In three weeks, if healing is sound and there is no effusion, the patient should be allowed to walk a little with sticks or crutches. These he may dispense with in another week or so; but it is safer not to allow football or any violent exercise of that kind for four or five months, after which time the joint is perfectly strong.

Edinburgh.

# RHEUMATISM AS A CAUSE OF EPISTAXIS IN CHILDREN.[1]

BY SIDNEY PHILLIPS, M.D., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT, ST. MARY'S HOSPITAL; SENIOR PHYSICIAN TO THE LONDON FEVER HOSPITAL; PHYSICIAN TO THE LOCK HOSPITAL

IN this short paper I shall not attempt to enumerate the many causes of epistaxis. But in practice I think we must all have met with cases which cannot be ascribed to any of the usually enumerated causes, and in out-patient rooms and elsewhere I have found epistaxis so commonly associated with evidences of rheumatism, in some form, that the association appears to be more frequent than could be due to mere coincidence.

The following are brief abstracts of notes of cases illustrating this association

CASE 1.—A boy who had had rheumatic fever at the age of five years was brought to me at St Mary's Hospital on August 1st, 1893. for epistaxis. He was then 10 years of age and his mother said that he had had attacks of epistaxis for years—even before the rheumatic fever. He was also subject to sore-throats He had no pain anywhere, but his temperature was 99·6° F., and on examination I found effusion of fluid into both knee-joints and a soft mitral systolic bruit at the heart's apex. I admitted him into the hospital and he soon recovered from his joint affection under treatment by salicylates

CASE 2—A girl, six years old, was brought to St. Mary's Hospital on Sept. 25th, 1900, for epistaxis. She had been subject to attacks of it for three years but it had recently become more profuse. She was very anæmic and had enlarged tonsils. I ordered her perchloride of iron. Epistaxis recurred on Oct. 18th and on Nov. 21st the right knee became full of fluid. This gradually subsided, but in March, 1901, the child was again brought to the Hospital suffering from effusion into the knees and pains in the limbs. These gradually subsided and she was well by June. This child for years had attacks of nose-bleeding

CASE 3.—A boy, aged 11 years, was brought to St. Mary's Hospital on Nov. 6th, 1900, for nose-bleeding. I found his left knee full of fluid. He had no pain in this limb, and I only discovered its condition on searching for a cause for his epistaxis. The bleeding continued very freely on and off till Dec. 18th, though he was taking salicylates, but aspirin seemed to do him good. He came to the hospital again suffering from considerable pain and swelling of several joints in March, 1901.

CASE 4—A girl, aged 12 years, had on June 10th, 1900, headache, sickness, and epistaxis. Next day her right wrist became swollen and epistaxis recurred. She was admitted under my care into St. Mary's Hospital on June 14th, 1900, with effusion into the right wrist and ankle and a very soft systolic bruit—in fact, she had all the evidences of a subacute rheumatic attack. A little later while in hospital there were slight choreic movements.

CASE 5.—A girl, aged 13 years, who had had rheumatism three times, suffered in March, 1900, from faintness, giddiness, and epistaxis She was taken into St. Mary's Hospital on March 25th with effusion in the knee-joints, dilatation of the heart, and slight pyrexia. She soon got well under salicylate treatment.

CASE 6—A girl, aged eight years, was brought to St. Mary's Hospital in 1888 with frequently recurring epistaxis. She had had rheumatic fever at the age of five years. I subsequently saw her in 1890 with epistaxis, and again in 1892 with slight rheumatism of the joints and epistaxis, and in 1895 she was taken into the hospital with a mitral systolic and an aortic diastolic bruit; there had been no bruits when I saw her before. In this case rheumatism in the joints and in the heart and epistaxis went on for a period of seven years, during which she was under occasional observation.

CASE 7.—The patient was a girl who had had chorea at the age of nine years and again in 1895, when she was 11 years old. She had never had rheumatic fever. She had had nose-bleeding two or three times a week and had been treated for this at the Hospital for Sick Children in Great Ormond-street. She came to me on July 15th, 1895, with epistaxis. No cause was discoverable for this except her rheumatic tendency and she got better under treatment by salicylates.

CASE 8—A girl, aged 11 years, was brought to St. Mary's Hospital on Sept. 30th, 1901, suffering from chorea—a first attack. No cause was ascertainable; there was no history of articular swelling and nothing wrong could be detected in the heart. The patient had been subject to epistaxis at night for 11 months. She recovered from the chorea and the epistaxis under treatment by salicylates.

CASE 9.—A girl, aged 10 years, was brought to me at Paddington Green Children's Hospital on Oct. 6th, 1886, suffering from anæmia. She complained of giddiness when walking and she had choreic movements of the hands, occasionally dropping cups and saucers. She had never had rheumatic fever, but she had had scarlet fever at the age of four years. After attending as an out-patient for a month she came into the hospital under my care. Her heart was very irregular and weak, with a frequent dropping of the second sound and a systolic bruit. She had frequent attacks of epistaxis, slight choreic movements, irregular heart action with a systolic bruit, and recurring attacks of epistaxis. She gradually got well and the murmur disappeared; it had been due probably to dilatation of the ventricle.

CASE 10.—In a case which I saw in November, 1901, with Dr. P. Montague Smith a child, aged five years, suffered from sudden pyrexia and sore-throat with epistaxis. I was asked to see the patient as scarlet fever was feared, but we found that one of the knee-joints, though quite painless, was full of fluid. The child in a day or two developed more fully an attack of acute rheumatism with effusion into other joints. Inquiry elicited the fact that she had also had an attack of rheumatism a year previously.

In all these cases the urine was carefully examined and it was found to be free from albumin. There was no local nasal disease and no cause could be found for the epistaxis except that there were evidences of a rheumatic diathesis. I could bring forward many other cases similar to the above. In some of them the epistaxis came on with an attack of acute rheumatism, in others epistaxis alternated with attacks of articular inflammation, or was preceded by them and in some cases it occurred in connexion with chorea which was presumably rheumatic. That in children synovial effusion into joints and articular rheumatism may occur without any pain has often been pointed out, but it is even now scarcely sufficiently remembered; and I think if the joints were

---

[1] A paper read before the Harveian Society of London, Feb. 6th, 1902.

*damaged joint stiff by muscular contraction, and while full* flexion may also be interfered with by effusion into the joint (a condition which usually shows itself with great rapidity after the primary accident), my experience has been that in cases where the condition can be seen before effusion sets in, and where the confidence of the patient can be obtained, the knee can always be flexed by the surgeon fully and painlessly, but any attempt at full extension is accompanied by severe pain. This is a diagnostic point of some value in enabling one to make a diagnosis between damage to the cartilage itself and strain or bruise of the tissues (ligaments, bones, &c.) lying in immediate anterior relation to the cartilage. In the former case full extension is painful, while full flexion is painless; in the latter case it is exactly the converse. This point is of importance, also, in distinguishing between an injured semilunar cartilage and a "loose body" in the joint, the latter condition being usually easily recognised by the shifting position of the pain and by the fact that now in attempts at flexion, now in attempts at extension, the characteristic "locking" and pain are produced, according to the changing position of the "loose body." I have not yet met with a case where the posterior insertion of the cartilage was completely separated (though in Fig. 5 it appears to be considerably damaged). If such separation does occasionally happen it is probable that then there would be a resulting difficulty in flexion.

FIG. 1

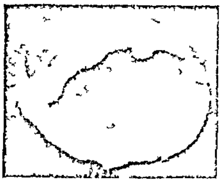

FIG. 2

FIG. 3

FIG. 4

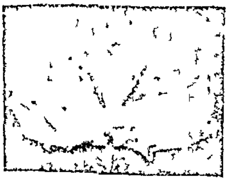

FIG. 5

FIG. 6

Fig. 1, Internal semilunar cartilage showing complete central splitting.

Figs. 2, 3, 4, and 5. Internal semilunar cartilages showing tearing of the free edge with protrusion of "tag" into the joint.

Fig. 6. External semilunar cartilage showing considerable changes due to injury.

It will be found that in many old standing cases, while all other symptoms may have disappeared and ordinary movements of the joint are both free and painless, if the surgeon makes the patient sit on the edge of a chair and put his heel on the ground with the knee fully extended, and if firm backward pressure be now made by the surgeon on the knee, *so as to hyper-extend the joint,* distinct pain will be elicited across the front of the knee. I have noticed this symptom to last many months after the original accident—it sometimes seems to remain indefinitely. It may be an encouragement to the surgeon to interfere where the other symptoms, such as occasional locking, pain, or synovitis, unpleasant though they be to the patient, may yet not be sufficiently definite to warrant operation.

TREATMENT.

With regard to the best method for the easiest reduction of the displaced cartilage, here again we find considerable difference of opinion. Thus, for example, Dr. A. Logan Turner[2] who has written an excellent paper on the subject, Mr. C. Stonham, C.M.G., and others recommend that the leg should be flexed, then rotated in the direction of the dislocated cartilage, and then extended. Da Costa advises rotation, but does not specify the direction; while in Treves's "System of Surgery" we are told to "bring the leg into full extension, rotating inwards and outwards at the same time," a piece of advice which is perhaps somewhat puzzling. Probably most surgeons are in favour of flexing, then rotating away from the side of the injury, while bringing the leg into full extension; for example, in the common case of the internal cartilage being displaced, flexing, rotating *outwards,* and then extending. This plan I have invariably found effectual, though an anæsthetic is usually necessary. It also would appear to be the most rational, for it can be easily seen when the knee-joint is opened how flexion and eversion of the leg open up the space between the tibia and the internal condyle, inversion of the leg approximating these surfaces while separating the tibia from the external condyle. One would consequently suppose that whether the internal meniscus was dislocated centrally or marginally this wide separation of the bony surfaces concerned would more easily allow the cartilage to slip or be pushed into place. It is, however, not easy to be sure as to the exact traction effect of the attachment of the cartilages to the internal lateral ligament (which structure is tightened by external rotation) and to other structures, and possibly some cases of internal dislocation may best be reduced by internal rotation; that, however, has not been my experience.

In the case of the primary injury to the cartilage, after it is reduced, it is of the greatest importance, in order to prevent recurrences, to give the torn parts sufficient time to heal firmly, while everything is done to prevent irritation and effusion. It is no waste of time for a patient to spend several weeks with his knee at absolute rest with this end in view. If this be done recovery is often complete, as I can testify from personal experience, and the joint may *then* be used for any purpose in sport or games as freely as the other. Of course, this remark only applies to a first attack; when recurrence has once taken place a permanently good result without operation is unlikely.

The use of splints is beneficial in proportion to the extent to which they limit rotation movements of the joint. For purposes of an *athletic life they are mostly unsatisfactory* and are far inferior to the results attained by successful operation. In the comparatively rare case of marginal protrusion of the meniscus a pad is possibly of value; in the commoner central displacement it is not so.

*Indications for operation.*—A patient below middle life who wishes to lead an active existence, who is in good health, who has no rheumatic or tuberculous tendencies, and whose cartilage is frequently giving him trouble, should have the operation performed.

*Operation.*—A curved incision is made through the skin and fascia, starting at the inner edge of the ligamentum patellæ just above the margin of the head of the tibia, passing downwards about an inch below the joint, and then curving upwards and backwards to end at the anterior edge of the internal lateral ligament. The flap being turned up, the capsule of the joint is then opened by a straight transverse incision, and (unlike Mr. Barker) I prefer to incise the joint above, and not below, the cartilage, cutting directly down upon the femoral articular surface about half an inch above the line of the meniscus. This incision gives one an admirable view and, I should suppose, would be much less likely to raise doubts in the mind of the operator as to how far his incision might not be responsible for the separation of the cartilage from its tibial attachment. Having exposed the cartilage—and for this purpose strong eversion of the *flexed leg will be found of great service*—it patch was of about the size of a two-shilling piece. The gums were now in an extremely foul state and the inside of the cheek was discoloured, but there was no ulceration. There was a constant saliva of foul-smelling, blood-stained saliva. Although suffering no pain the boy was so ill and weak that he was able to take very little nourishment beyond a little milk and small quantities of brandy. Owing to great thirst he drank copiously of lemonade, soda-water, &c. The patch of gangrene in the skin spread rapidly in all directions, and on the 4th its anterior limit passed in an oblique line across the lower lip to the gum, about half an inch to the right of the middle line. The inside of the cheek and the gum corresponding to this area were also black and gangrenous, but there appeared to be no attempt on the part of the surrounding tissues to separate the necrotic mass by ulceration. A patch of gangrenous skin had now appeared over the left side of the lower jaw in a similar position, and of about the same size as that first observed on the right side. The boy died on the 5th. Only palliative treatment was possible under the circumstances, as the hopeless condition of the patient from the first forbade the adoption of any surgical measures, even had the parents been willing to allow an operation.

---

[2] Edinburgh Hospital Reports, vols. ii. and iii.

Affection of both sides in cancrum oris is, I believe, rare, and the course of this case is also unusual in the extent of implication of the skin before any ulceration of the cheek took place. The absence of reaction on the part of the tissues was probably due to the greatly enfeebled condition of the circulation for a long time previous to the onset of gangrene.

## WESTMINSTER HOSPITAL.

### A CASE OF ULCUS CARCINOMATOSUM OF THE PYLORUS.

(Under the care of Dr. W. MURRELL.)

THE connexion between simple ulcer of the stomach and a malignant growth is generally admitted and is well illustrated by the following case. Unfortunately, in many cases of carcinoma of the stomach the diagnosis cannot be made until it is too late for complete removal of the growth by operation. Of recent years laparotomy for simple ulcer of the stomach has been employed with success in certain cases and the advisability of an exploratory abdominal section may be considered in gastric ulceration when medicinal treatment has proved of no avail. In this way it may be possible to recognise and to remove malignant ulceration of the stomach at an early stage.

A woman, aged 35 years, was admitted to Westminster Hospital on April 12th, 1900, suffering from what was supposed to be gastric ulcer. She stated that in 1894, about a month after the birth of her first child, she had pain in the chest and back coming on soon after food and relieved by vomiting but unattended by hæmatemesis. This lasted for three and a half years when the symptoms subsided and for six months she suffered from no discomfort or inconvenience. A month before the second child was born she had another attack which lasted nine months, during which she frequently brought up blood but never in large quantities. About 16 months ago she again became pregnant and since then had suffered constantly from gastric symptoms. The pain after meals had been more pronounced and the vomiting more frequent. She stated that with intermissions her illness had lasted for six years and during the last two years she had lost flesh considerably.

On admission the patient was found to be very thin, but she presented no cachectic appearance; her weight was five stones eight pounds. She complained of a feeling of oppression in the epigastric region culminating in acute pain after food and relieved by vomiting. The vomited matter consisted of undigested food with a quantity of yellow frothy fluid having an acid reaction. There was very little abdominal tenderness, the stomach was only slightly dilated, and there was some thickening about the pylorus. The temperature was normal and the urine had a specific gravity of 1020 and contained no albumin. The patient was kept in bed and was placed on three pints of peptonised milk, five ounces every two hours, with plasmon custard, but the vomiting was so persistent that nutrient enemata with suppositories of beef peptones were substituted. These suppositories contained 50 per cent. of peptone of beef and each weighed 72 grains. The bowels were relieved from time to time by a simple enema. On this treatment she progressed favourably until May 14th, when there was a sudden rise of temperature. At 7 A.M. it was 103·4° F. and at 3 P.M. it was 104·6°, the pulse being 136. There was no sore-throat, or pneumonia, or endocarditis, and apparently nothing to account for it. She was put on small and frequently repeated doses of tincture of aconite and on the following day the temperature fell to 100°, although henceforth it was never quite normal and ranged from 100° to 101°. On the 16th she started an attack of diarrhœa which proved extremely obstinate and continued until her death. There were often from 10 to 12 evacuations in the 24 hours. The motions were loose, but not watery; they were small and greenish-brown in colour, not slimy, but very offensive. Various modes of treatment were tried without avail, including saturated solution of camphor in alcohol—three drops every five minutes—drachm doses of carbonate of bismuth every four hours, enemata of opium—15 drops of the tincture in two ounces of mucilage of starch—and from time to time pill of lead and opium. That these remedies were ineffectual is shown by the fact that she had 103 motions in 20 days, exclusive of those which were too small to note. Once or twice the stools were dark in colour and contained what was apparently broken-up clot. The patient gradually lost ground and early in May a small nodular mass was felt to the right of the middle line midday between the umbilicus and the ensiform cartilage. The stomach was dilated but not markedly so. On May 26th it was obvious that she was critically ill. She was losing flesh rapidly and was too weak to get out of bed. There was considerable anæmia and the face looked almost as if it were jaundiced, although the conjunctivæ were white. She was in no pain but took very little nourishment. The tongue was moist and tremulous and there were streaks of fur in the centre. The diarrhœa continued and there was prolapse of the rectum. There was no albumin or sugar in the urine. The stomach was more dilated, but the liver was not enlarged. At 7 A.M. on May 29th the temperature was 99°; at 11 A.M., 98·4°; at 7 P.M., 97·8°; and at 11 P.M., 96·4°. At 7 A.M. on the 30th it was 96 4°; at 3 P.M., 97·6°; and at 11 P.M., 96 8°. She died at 1.40 on the morning of the 31st.

*Necropsy.*—At the necropsy the stomach was found to be adherent about the pylorus to the liver. It was dilated and at the pylorus there was an ulcer consisting of two distinct parts. One, which was directed towards the stomach, was cicatrised and this was adherent to the liver, and the other, directed towards the pylorus, was fungoid in appearance. The two ulcers together were of about the size of a five-shilling piece. There were enlarged glands in the portal fissure and in the neighbourhood of the growth. There were no secondary deposits in the liver, which was fatty. The intestines showed melanic contents in places and the villi were atrophied. The spleen, adrenals, pancreas, kidneys, bladder, uterus, and ovaries were normal. Microscopical examination of the growth showed that the condition was one of spheroidal carcinoma. The muscular tissue about the pylorus was being invaded by a growth poor in cells and suggesting scirrhus.

*Remarks by* Dr. MURRELL.—This case is interesting in many ways and exemplifies the facility with which malignant growths of the stomach may be confounded with peptic ulcer. The disease commenced as a simple ulcer and after a time the cicatrix became the seat of carcinoma—an illustration of the well-known fact that damaged structures are not infrequently the point of localisation of cancer. The popular belief that scirrhus sometimes follows blows on the breast in the female is probably not without foundation. At what particular period of the patient's history the change commenced it is difficult to say. It was probably subsequently to the first illness in 1894, for there was a period of six months examined in some cases of epistaxis, a clue would be often found to the cause of the latter.

Epistaxis is one of the toxic effects of salicylates given internally. Dr. L. Shaw[2] found that it occurred in 11 patients of 174 under the treatment of rheumatism by salicylates. None of my patients, however, had taken salicylates before the epistaxis occurred, and all but one, who did not respond to it, took the salicylate with good result. It is possible that in some cases of rheumatism treated by salicylates where epistaxis occurs it is due to the disease and not to the drug.

In all the literature on rheumatism I have not found any suggestion that rheumatism may cause epistaxis except indirectly, through setting up endocardial changes. In a very excellent article on epistaxis by Dr. F. de Havilland Hall,[3] various alterations in the blood are mentioned which are attended with epistaxis as a prominent symptom—viz., hæmophilia, purpura, scurvy, chlorosis, anæmia, pernicious anæmia, and malarial poisoning, but not the rheumatic diathesis. The only suggestion I can find that rheumatism has any influence whatever in the causation of epistaxis is in a paper by Dr. Rendu[4] of Paris, quoted by Dr. Hall, in which it is said that epistaxis may occur in young persons who become later the subjects of piles or rheumatism. I think it may be said that epistaxis occurs in the young who are already the subjects of rheumatism.

There is nothing inherently improbable in the supposition to which many cases point, that rheumatism may give rise to epistaxis, for many other blood states are acknowledged to do so, and rheumatism is a known cause of one variety of purpura in which hæmorrhages occur from cutaneous and mucous surfaces.

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A CASE OF CHELOID.

BY H. TAYLOR, M.A. CANTAB., M.A., M.D. DUB.

A MAN, aged 21 years, healthy and dark-complexioned, with some tendency to acne as evidenced by the comedones scattered over his face, neck, and shoulders, sustained some two years ago—owing to the application by mistake of a poultice in an almost scalding condition—a large blister involving the skin over the lower ribs and the epigastric and hypogastric regions. This blister on healing left two elongated pigmented patches, unaccompanied, however, by any loss of the natural suppleness of the integuments until after the lapse of some five or six weeks, when the patient noticed that some "lumps" were forming in the outer patch; these gradually developed into a tumour which was tender and painful and which itched at times. It was, the patient states, however, completely removed by operation in October, 1900, but all the phenomena very shortly reappeared and in 10 or 12 weeks the recurrent growth was as large as ever. It now presents as two hard, fibrous, whitish-grey, spindle-shaped masses, with no evidence of any increase in vascularity, joined together in an A-shaped form by a shorter band of similar structure, and though at present the mass of the tumour has not trespassed beyond the area previously occupied the numerous outlying foci it is now surrounded with would point to an early encroachment on adjacent tissue. Tenderness, pain on pressure, and itching are complained of as in the original growth, but there is none of the burning sensation usually noted as one of the symptoms.

Virchow attributes cheloid to an irritation caused by, and proportionate to, the extent of the exciting lesion, while Alibert, who first described the disease, attempted to divide it into "true," or spontaneous, and "false," or cicatricial, cheloid. Others, again, would differentiate between a spontaneous or idiopathic growth and one arising from "scar tissue," but it is now considered very doubtful, in view of the many trifling injuries to the skin which may occur unnoticed or forgotten, whether it ever arises without some such exciting cause. It is sometimes associated with acne; it has developed in the scars of leech-bites, in those of vaccination, of herpes, and of small-pox. Showing itself as it usually does between the ages of 15 and 50 years it is a disease of adult life and more common in the dark than in the fair races.

It is affirmed by Liveing, in combating the view that a cicatricial cheloid is nothing more than a hypertrophied scar, that while in the former the tissue consists of fibres closely packed together and arranged in the long axis of the tumour, with a tendency to assume a spindle shape, in the latter the fibres run in every direction, forming a confused irregular network. This microscopical test, however, is not often applicable, and the same authority gives the following points in favour of a diagnosis of cheloid in distinction to that of one of "hypertrophied scar": (*a*) if the growth is on or near the sternum, especially if it be multiple; (*b*) if tenderness, pain on pressure, and subsequently itching be present in the tumour; he states further that (*c*) cheloid eventually extends, though perhaps very slowly, beyond the scar, and hypertrophy of scar tissue never does this. A spontaneous involution, more usually in young subjects (Hutchinson), sometimes take place, and Goodhart has recorded a case in which extensive cheloid tumours arising after small-pox had in a few months disappeared.

Removal by operation or caustics is never, as in this case, successful in preventing a return. Pressure applied by elastic bandages, mercurial plasters, or deep incisions into the growth have all been recommended, and Morris has seen moderately sized tumours completely disappear after electrolysis applied once a week accompanied by a daily massage. He also recommends, if the growth be painful, the injection in and around it of cocaine or the local application of belladonna or opium.

### FREQUENT REPETITION OF TAPPING FOR ASCITES.

BY JOHN DAVIES, M.R.C.S. ENG., L.S.A.,
SENIOR SURGEON, BATH WESTERN DISPENSARY.

THE patient was a strongly-built, healthy-looking man, 50 years of age, of the country yeoman type. He described himself as a moderate drinker of malt liquor only, though he went as far as to admit that he at times substituted it for a more solid meal. My first visit to him was on account of an epileptic fit, the only one he ever had. In September, 1896, he found some difficulty in getting up and down from the box of a cab which he drove, and he complained of a feeling of distension in his bowels, which he likened to water rolling and splashing from side to side. A month after being treated internally for ascites he was tapped, that was early in October, 1896, from which date up to October, 1900, he was tapped regularly, at first once in three weeks, then once a fortnight, and ultimately every nine days, making a total of 150 tappings. At first from 12 to 14 quarts were withdrawn at each sitting by Southey's tubes; towards the finish less was withdrawn but the total quantity was over 250 gallons. In October, 1900, he died from cardiac failure. Some features in the course of the case were œdema of the right leg, which cleared up, and then the same happened to the left leg, and thrombosis of the veins of the right side of the abdominal wall.

Bath.

### A CASE OF CANCRUM ORIS AFFECTING BOTH SIDES.

BY E. E. LASLETT, M.D. VICT., B.SC. LOND.

THE patient, a boy, aged six and a half years, was suffering from advanced pneumonic phthisis and for some weeks there had been great emaciation and weakness. For some days he had been suffering from severe stomatitis which was little influenced by local antiseptic treatment. The teeth became loose and dropped out or were pulled out by the boy himself. The gums were swollen and softened, and the lower gum especially was much discoloured in places. On Feb. 2nd, 1902, a black patch appeared on the skin over the right side of the lower jaw below the angle of the mouth. When I saw the patient in the morning of that day the relieved by lying down. There had been no vomiting. The bowels were habitually constipated. For the previous six weeks he had lost flesh and become increasingly weak. He found difficulty in standing for any length of time and in raising himself from the stooping posture and had been obliged to give up work because he was unable to walk to it. A few nights previously he had got out of bed and had fallen down and was so weak that he had to lie on the floor for the rest of the night. Since then he had kept entirely in bed. He was unable to give any date for the onset of the cyanosis.

---

[2] Guy's Hospital Reports, 1887.

[3] Westminster Hospital Reports, 1893.

[4] La Semaine Médicale, June, 1884.

The patient was a tall, fairly well-nourished man. His mental condition was dull and apathetic and he took but little notice of what went on around him. He was slow in answering questions and his speech was slow, thick, and mumbling. His memory and attention were impaired. The temperature was slightly subnormal. The face was extremely cyanosed, especially the nose, which was large and broad and showed many dilated venules. The conjunctivæ were injected and yellowish; the pupils were contracted. There was marked clubbing of the fingers. The skin over the trunk was slightly pigmented, especially on the left side from the axilla to the hip. There were small scars over both the front and the back of the chest and the front of the legs. The skin over the arms and hands was thin, soft, and cold and bright red in colour around the joints. The lower part of the legs showed considerable bronzing. The teeth were in an extremely bad condition, the majority being either missing altogether or represented by decaying stumps. The tongue was thickly furred. The superficial veins of the abdomen were enlarged. The spleen extended down to the level of the umbilicus and to the middle line in front. It was hard and but slightly tender. There were some increased resistance in the right hypochondrium and some tenderness in the region of the gall-bladder. The liver dulness extended half an inch below the ribs, but the edge could not be felt. The heart sounds were normal except for some little accentuation of the pulmonary second sound; the pulse was 96, soft and easily compressible. There was some enlargement of the glands in the groin, but no enlargement of the thyroid. The urine had a specific gravity of 1012 and contained a cloud of albumin. Microscopically, there were some epithelial cells and leucocytes, but no casts. The total quantity passed in the 24 hours averaged from 40 to 50 ounces, and the total amount of urea was at first 400 grains. Micturition was frequent, and the patient generally passed urine three times in the course of the night. Beyond the slow mental condition no abnormal psychical signs could be detected.

On Feb. 1st the red cells numbered 9,000,000 and the hæmoglobin measured over 120 per cent. The white cells were not increased. There was no alteration in the shape or the size of the corpuscles. The spectrum of the blood showed nothing abnormal. On the 5th it was reported that the urine gave no indican reaction and showed no abnormal spectrum. On Jan. 31st and Feb 3rd and 7th the presence of a considerable quantity of uric acid was noted in the urine, and on the 6th the urea passed amounted to 738 grains. Only once—namely, on the 7th—were a few hyaline casts found in the urine. No noticeable alteration in the symptoms occurred during the patient's stay in the hospital, though occasionally he would appear to be unusually drowsy, and he was discharged in the same condition on March 20th.

Four days later (on March 24th) he was again taken to the out-patients' room on account of increasing drowsiness and he was again admitted into the hospital. The cyanosis was even more marked than before and there was distinct jaundice. He was extremely drowsy and apathetic, lay all day with his eyes closed and paid but little attention even when aroused. He constantly passed urine in bed and stated that he was not aware of doing so. The temperature was 99° F. and the pulse was 90. The liver dulness extended to half an inch below the costal margin. The blood count on March 25th and on April 2nd showed 7,360,000 red cells on each occasion. During the following days the condition steadily became worse. The cyanosis increased but the jaundice became less marked. The temperature fell below the normal level until the day of death when it rose to 100·8°. The patient died on April 8th.

*Necropsy.*—At the post-mortem examination the heart was found to be somewhat enlarged, weighing 13 ounces. The wall of the left ventricle was thickened and there was some old mitral valvul[illegible]se. No communication existed between the two sides of the heart. The lungs were engorged and the bronchial tubes contained a good deal of muco-purulent secretion. There were some adhesions between the pleuræ and the chest wall and diaphragm. The liver was large and very firm and weighed 66 ounces; the surface was smooth. The kidneys were large and congested; the right kidney weighed six and a half ounces and the left seven ounces. The capsules were not adherent. The supra-renal capsules were small, dark red, and very soft. The spleen weighed 48 ounces, but was of normal consistence on section. The brain was congested and the arachnoid was opaque in patches. The marrow of the femur was normal on naked-eye inspection, but was not examined microscopically. The condition of the thymus was not noted.

*Remarks by* Dr. RUSSELL.—Since seeing this patient I have come across the reports of three apparently similar cases, all of which were published in the Boston *Medical and Surgical Journal*, but I have not succeeded in finding any other reference to the condition in the literature of cyanosis. Brief notes of the three cases referred to are as follows:—

CASE 1.—The patient was a woman, aged 46 years, who was first seen by Dr. Cabot[1] in October, 1895. She was a masseuse and for two years had suffered from attacks of sudden mental and muscular prostration whilst at work. She had lately noticed increasing blueness of the lips, and during the attacks of prostration stated that her face got dark purple and her eyes bloodshot. The more severe attacks lasted for 24 hours and were accompanied by violent headache and nausea. Two weeks previously she had had an attack of sciatica, during which ecchymoses appeared on the outer side of the thigh. On examination the lips and nose were remarkably cyanotic and the whole face was dusky and apparently somewhat puffy. There was slight swelling of the ankles. The heart was practically normal. The temperature was 93·6° F. and the pulse was 90. The urine had specific gravity of from 1011 to 1016, and contained a slight trace of albumin and a few hyaline casts. It amounted to from 60 to 70 ounces, with eight or nine grains of urea to the ounce. The red corpuscles numbered 10,460,000 and the white cells numbered 20,000. The hæmoglobin measured about 150 per cent. The condition remained much the same for the next two years, but in January, 1897, the patient suffered from very free hæmorrhage after the extraction of a tooth. Shortly after, whilst walking in the street, her legs suddenly began to make peculiar movements of their own accord, and she had to hold on to some palings to keep from falling. In February, 1897, during one of her attacks of headache, weakness of the left arm and leg developed and she gradually became comatose and died on March 3rd. At the post-mortem examination there was a small hæmorrhage from the middle meningeal artery, with passive congestion of all the organs.

CASE 2.—This case was shown by Dr. Cabot[2] at a clinical meeting of the Medical Board of the Massachusetts General Hospital on Dec. 15th, 1899. The patient was a woman, an indiarubber worker, aged 49 years. She was first seen on Jan. 5th, 1894, and complained of vertigo, weakness, and constipation. She was then thought to be suffering from lead-poisoning. She did not attend again until Jan. 12th, 1895, when she complained [illegible] symptoms with palpitation and præcordial distress coming [illegible] excitement or exertion. She had suffered much from headaches. All her symptoms had been present for several years, but had [illegible] increased during the previous four months. On examination the face and mouth were cyanosed and the conjunctivæ were injected. The heart was normal except for a slight pulmonary systolic murmur. The edge of the liver was palpable, and the spleen could be felt two fingers'-breadth below the ribs. The gums bled easily. The hands and feet were blue but the fingers were not clubbed. The urine was of low specific gravity and contained a trace of albumin, a few hyaline casts, and a trace of bile. The hæmoglobin amounted to 120 per cent. She was discharged on March 28th, 1895. On April 4th, 1899, the patient again made her appearance in much the same condition. The red corpuscles numbered over 12,000,000. The skin showed considerable bronzing, especially about the axillæ, and some small leucodermatous patches about the trunk. The spleen extended a hand's-breadth below the ribs and the liver three fingers'-breadth below the right costal margin. The urine contained 0·1 per cent. of albumin. Later the red cells numbered 9,252,000 and the white cells numbered 10,600. The hæmoglobin then measured 110 per cent. The patient was readmitted on two subsequent occasions in the same year, but there was no material alteration in her condition.

CASE 3.[3]—The patient, a man, a packer in an iron-foundry, aged 53 years, was first seen on May 6th, 1901. He had been liable to sudden attacks of dyspnœa at intervals of from six months to two years during the last 20 years. There was no history of venereal disease and the patient had been strictly temperate. He had first noticed blueness of the face and hands one and a half years previously, and stated that it had come on suddenly whilst recovering from one of the attacks of dyspnœa. It often increased suddenly without any accompanying symptoms, and was not brought on by exertion, though it was generally more marked during an attack of dyspnœa. He had had no headaches. For two years he had been subject to frequent attacks of diarrhœa. On examination, there was extreme cyanosis of the face, especially of the lips and tip of the nose and ears. The small veins and capillaries of the skin were dilated. The hands and feet were very blue, and there was slight clubbing of the fingers. The conjunctivæ were injected; the gums were swollen and they easily bled. The heart was normal. The edge of the liver was not felt, but the dulness extended to two fingers'-breadth below the ribs; the spleen was felt one inch during which she was apparently well and the stomach symptoms were quiescent. Too much importance, however, must not be attached to the temporary improvement, for Leube of Jena[1] records a case of cancer of the stomach, confirmed by post-mortem examination, in which the patient gained five pounds in weight in eight days. Our patient had been losing flesh for two years before admission, but even that is no proof that the disease had then assumed a malignant form. There was thickening about the pylorus, but that might have been due to the formation of cicatricial tissue from the healing of an ulcer. The first symptom to attract attention was the sudden elevation of temperature followed by persistent diarrhœa. It was probably septic in origin and there can be no doubt that the disease had then assumed a malignant form.

---

[1] A Case of Chronic Cyanosis without Discoverable Cause, ending in Cerebral Hæmorrhage. By Richard C. Cabot, M.D. Boston Medical and Surgical Journal, Dec. 7th, 1899.

[2] Boston Medical and Surgical Journal, March 15th, 1900.

[3] A Case of Marked Cyanosis Difficult to Explain. By Sylvester F. McKeen, M.D. Boston Medical and Surgical Journal, June 20th, 1901.

Malignant disease of the stomach is not common at so early an age, although several cases in young children have been recorded. In some of these, however, no histological examination was made and they may have been examples of sarcoma of the stomach or of hypertrophy of the pylorus. Norman Moore[2] published the case of a girl, aged 13 years, in which the microscopical characters of the new growth were those of carcinoma with somewhat wide trabeculæ and extensive degeneration of the cells. Perry and Shaw[3] mention a case in a woman, aged 32 years. The wall of the stomach was in large part destroyed and replaced by a mass of colloid, which freely invaded the abdominal wall and the neighbouring viscera. There was a secondary deposit in the liver. Histologically the growth was a spheroidal carcinoma with scanty stroma and colloid change. In 1898 there was a case in the Westminster Hospital[4] of cancerous infiltration of the pyloric portion of the stomach in a woman, aged 36 years. Micro-sections showed colloid carcinoma, the colloid degeneration being limited to the gastric mucosa in a few isolated patches between the muscle bundles. Again, in 1900,[5] there was a woman, aged 34 years, with a growth invading the whole wall of the stomach and implicating the liver. Microscopically it was found to be a much degenerated squamous-cell carcinoma. The cylindrical carcinomas are amongst the most common of the tumours of the stomach, but apparently neither age nor sex has any determining influence on the character of the growth.

The development of cancer in gastric ulcer is a well-recognised sequence of events, especially at the pylorus. Rokitansky and Dettrich were the first to describe this condition and Hauser gave an accurate histological description of it. Kollman in 1891[6] reported 14 cases and since then many others have been recorded. Some authors—Rosenheim, for example—say that it occurs in from 6 to 8 per cent. of the cases, whilst others consider that as an etiological factor it is of very little importance. Brinton[7] long ago pointed out that the presence of an open ulcer sometimes provokes the development of the cancerous cachexia as well as aids in determining the deposit of cancer in the particular organ. He had probably been impressed by a case which he had shown at the Pathological Society[8] some years previously in which the floor and especially the margin of a large gastric ulcer exhibited a deposit from a quarter to half an inch thick which on microscopical examination was found to be cancerous. There are two other cases recorded in the Transactions of this society, one by Goodhart (vol. xl., p. 78), in a man, aged 32 years, and another by Newton Pitt (vol. xlvii., p. 52), in a man, aged 57 years. Stewart[9] mentions a case in which there were two isolated carcinomatous ulcers. Tapret,[10] Bouveret,[11] Hayem,[12] Dieulefoy,[13] and various other writers record cases. This complication, however, cannot be very common, for Fenwick[14] says that only two genuine specimens were observed in the post-mortem room at the London Hospital during a period of 40 years.

The diagnosis of gastric carcinoma *ex ulcere* presents many difficulties, and it is often not easy to distinguish it from hypertrophic stenosis of the pylorus. For example, Hemmeter[15] speaks of a case in which no tumour was to be felt, and the only symptoms were those of cachexia in gastric ulcer. As Boas[16] has pointed out, in some cases the metastases in the liver or other organs with ascites or peritoneal carcinosis may excite suspicion, but such aids are rarely obtained, and in the majority of instances there is nothing to guide us until quite late in the progress of the disease. The discovery of the Oppler-Boas bacillus in the vomited matter may be of diagnostic importance.[17] In unstained preparations these organisms are readily recognised by their large size, their immobility, and their peculiar base-ball bat shape. They possess the property of forming lactic acid from various kinds of sugar, a constant parallelism being observed between the occurrence of these bacilli in large numbers and an excessive formation of this acid. Kaufmann demonstrated their presence in the vomited matter in 19 out of 20 cases of gastric carcinoma. Although, as shown by Schlesinger and Kaufmann,[18] they are not pathognomonic of cancer, and although there are many other organisms which form lactic acid, their presence is suggestive. Whether in this particular case pylorectomy as performed by Péan in Paris in 1879, and subsequently by Cavazzáni, Rydygier, Wölfler, Czerny, and others, would have stayed the progress of the disease it is difficult to say. Probably pylorectomy with gastro-enterostomy, as suggested by Billroth in 1885, would have been the better operation.

# BIRMINGHAM GENERAL HOSPITAL.

## AN UNEXPLAINED CONDITION OF CHRONIC CYANOSIS, WITH THE REPORT OF A CASE.

(Under the care of Dr. SAUNDBY and Dr. J. W. RUSSELL.)

THE disease affecting the following case and the three other cases the records of which have been discovered by Dr. Russell is evidently a definite clinical entity and one which is new to medical science. It is not improbable that records of other similar cases may be discovered in medical literature. One of the most striking features of the disease is the great increase in the number of red corpuscles.

A man, aged 48 years, an electro-plater, was first admitted into the Birmingham General Hospital under the care of Dr. Saundby on April 24th, 1891, during Dr. Russell's term of office as resident medical officer. The patient complained of pains all over the body, most marked in the abdomen, and of general illness of five days' duration. He had, however, been feeling "out of sorts" and had suffered a good deal from headache for the previous three or four months. An epidemic of influenza was at that time at its height in the town and as the temperature was considerably raised the immediate symptoms were thought to be due to that complaint; but the spleen was persistently enlarged throughout his stay in the hospital. The urine had a specific gravity of 1010 and contained a trace of albumin; there were no casts. Beyond unusual pigmentation of the mammillæ and the presence of a few pigment marks about the trunk no abnormal colouration was observed. The patient was discharged on May 16th, the spleen remaining large as on admission.

Dr. Russell next saw the patient on Jan. 29th, 1898, when he attended as an out-patient. He then complained of pains all over the body, especially in the right side and head, of six weeks' duration. He was extremely cyanosed, and Dr. Russell therefore sent him into the hospital, where he was again admitted under the care of Dr. Saundby. The patient's family history was unimportant except that his mother died from phthisis. He had himself contracted syphilis at the age of 19 years. He had suffered from "gastric fever" at the age of 24 years, and a few years later he had a short attack of jaundice. There had been no other illness with the exception of that for which he was admitted in 1891, and from which he had entirely recovered. He had lived in comfortable surroundings and denied any alcoholic excess. The present illness had been coming on for about eight months, during which time he had suffered from pains in the abdomen of a gnawing character, generally worse in the earlier part of the day. These were mostly independent of food and were neutrophile leucocytes were ever formed there. The remainder of the paper was occupied by a comparison and contrast of the granular and non-granular cells as regarded distribution, spheres, and rapidity of action, extent of supply, variations in size, &c.

Dr. **WILLIAM HUNTER** said that three points had been brought out by the paper, first, the origin of the polynuclear leucocyte from the bone-marrow; secondly, that the changes in the bone-marrow had been regarded as compensatory to the changes in the blood, whereas Professor Muir had shown that there were very constant series of changes which corresponded to infective influences; and thirdly, the relation between the spleen and the bone-marrow and the appearance of myelocytes in the spleen in ases of changes in bone-marrow. He had shown experimentally the changes in the bone-marrow after removal of he spleen.

Dr. J. H. **DRYSDALE** said that the finely granular cells from cases of myelogenic leukæmia certainly varied very considerably in size, whereas Professor Muir had stated that they were of very uniform size He said that there might be a marked leucocytosis in the blood with a marked diminution of the leucocytes in the bone-marrow. He asked if the cases referred to as severe small-pox were cases of hæmorrhagic small-pox, and he said that he believed that such cases were small-pox with secondary infection.

Dr. A. G. **PHEAR** referred to a case of injury to the knee-joint with suppuration. Four weeks after the injury operation was performed, and following that there was profuse hæmorrhage; the patient died four days later. There was in this case a double factor—namely, suppuration and severe hæmorrhage some few days before death. The bone-marrow when examined was found to consist of a firm pink tissue of increased consistency with considerable diminution of fat cells. Three forms of cells were present—myelocytes, rythroblasts, and giant cells—and in two points the condition differed from that found by Professor Muir: firstly, nce; the number of the giant cells was increased and, condly, the absence of any karyokinetic figures.

Dr. O. F. F. **GRUNBAUM** asked whether the mitotic ures were more common in specimens obtained post rtem than in those obtained during life.

Professor **MUIR**, in reply, said that in mentioning the size of the finely granular cells he had not especially referred to their condition in leucocythæmia, but in the bone-marrow they did remain very constant in size He did not think that the mitotic figures were more common in specimens of bone-marrow obtained post mortem than in those obtained during life.

# CLINICAL SOCIETY OF LONDON.

### *Seventy-four Cases of Appendicitis with Localised Suppuration, with Special Reference to the Treatment of the Appendix in such cases —The Treatment of Intra-peritoneal Abscess of the Appendix, Illustrated by Cases*

A MEETING of this society was held on Feb 14th, Mr. **HOWARD MARSH**, the President, being in the chair

Mr. H. **GILBERT BARLING** read a paper on 74 Cases of Appendicitis with Localised Suppuration. He said that of 40 cases of appendicitis operated upon in the acute stage 74 had, been cases of localised suppuration in the right iliac fossa or immediately adjacent to it. In 46 of these the abscess, though well shut off by adhesions, had not yet come forward so as to be adherent to the parietal peritoneum and operation involved the opening of the general peritoneal cavity. In the remaining 28 cases the abscesses had become adherent and were evacuated without opening the general cavity. The points to which attention was directed were (1) the diagnosis of pus and the time at which it should be evacuated; (2) the safety with which this could be done if the removal of the vermiform appendix was not insisted upon; (3) the rarity with which recurrence took place if the appendix was not removed; (4) complications at the time of, or following, operation; and (5) certain risks to life which follow attacks of appendicitis apart from recurrence The abscess should be attacked as soon as the diagnosis of suppuration was made, but it should be remembered that pus might be present in he presence of a normal temperature and pulse, though there ight be other symptoms indicating it. Leucocytosis, though t pathognomonic, was decidedly valuable. In a series of cases in which pus was present leucocytosis was only absent in two cases and in every case examined where a high leucocyte count was found pus existed. The safety with which appendix abscesses might be treated if removal of the appendix was not insisted upon was shown by the small mortality in the cases under discussion. In the 74 cases there were two deaths. The appendix was only removed 25 times and in 49 it was not removed. All but two of those patients in whom the appendix was not removed had been traced since, and of these two, both hospital patients, nothing could be learnt; of the other 47 patients only one had suffered from recurrence—a girl who had had another attack within a few weeks of her operation and who was subsequently operated upon successfully and the appendix removed. Complications were not numerous and had been chiefly phlebitis and pleurisy and pneumonia.

Mr. F. C. **WALLIS** read a paper on the Treatment of Intra-peritoneal Abscess of the Appendix illustrated by eight cases This paper dealt with those cases of appendix abscess in which the abscess, although shut off by adhesions from the general peritoneal cavity, was in no way adherent to the abdominal parietes. It was therefore necessary to open the general peritoneal cavity before the abscess could be dealt with. In giving details of the operation great importance was attached to the fact that all the cases quoted except one occurred in young people and that adhesions at this age were very frail and required delicate manipulation to prevent the pus under tension in the abscess sac from escaping uncontrolled into the general peritoneal cavity. To prevent this Gamgee sponges were packed in a crescent around the affected area and when possible the pus was gradually evacuated and sponged up as it appeared. When the amount and tension of the pus was too great for this to be done the patient was tilted bodily over to the right side and the escaping pus was caught in a small bowl held underneath When most of the pus had been evacuated the cavity was more freely opened and thoroughly cleansed. Th appendix and its remains were then removed and the cavit was dusted with iodoform and packed with iodoform gauze It was a matter of importance to keep the wound as dry as possible. The necessity for operating quite early after the primary attack in young people was strongly urged.—Mr. A. E J. **BARKER** said that he had seen several severe cases of recurrent appendicitis in those patients in whom the appendix had not been removed at the primary operation. As an instance of this he quoted the case of a lad, aged 15 years, in whom the appendix could not be removed at the first operation and he had had five recurrences, and in some of these there had been severe collapse. He (the speaker) thought it advisable that the appendix should be removed at the time of the first operation if it could be done easily, otherwise it was best to wait till the acute stage had passed and to remove it in the quiescent interval. He was in favour of washing out the abscess cavity with saline solution and he was of opinion that strong germicides should not be used. It was, however, essential that a free exit for whatever fluid was used should be allowed, He thought that more effective drainage was obtained by means of an aseptic gauze "apron" than by means of a tube. He was greatly in favour of separating the muscle-fibres instead of making an incision through them, and sufficient room to evacuate the abscess was nearly always obtained and the advantage to the patient was undoubtedly great.—Mr **JAMES BERRY** said that it was inadvisable to remove the appendix in all cases of suppurative appendicitis, although such a practice had been advocated by some surgeons. He said that there were two schools, firstly, those who waited till the abscess was "safe," and secondly, those who opened the abdomen widely and removed the appendix at once. He was greatly in favour of waiting till adhesions had formed and making a small opening, and in support of this view he brought forward the following statistics. In 41 cases of appendicitis in which a small opening had been made only two patients died, while in 39 cases in which an extensive operation had been performed only seven recovered and 32 died. During a period of two years there were 240 patie suffering from appendicitis admitted to the medical a surgical wards of St Bartholomew's Hospital; of these died, a proportion of one in eight; taking the cases admitte to the surgical wards only the mortality was one in seven Of 200 cases admitted to St Mary's Hospital 25 patients died, giving a proportion of one in eight; of these 102 were admitted to the surgical wards and 22 died, giving a mortality of one in four. He thought that it was better to wait rather than to attempt to remove the below the costal margin. The temperature was normal. The urine amounted to 70 ounces; it had a specific gravity of 1015 and contained a trace of albumin and 35 grammes of urea. There were a few granular casts. The red corpuscles numbered 9,440,000 and the white numbered 9000. The hæmoglobin measured 120 per cent. The polynuclear white corpuscles amounted to 74 per cent., the small mononuclears to 18 per cent., the large mononuclears to 6 per cent., and the eosinophiles to 2 per cent.

These cases possess many points in common besides the extreme cyanosis. In three out of the four great weakness and prostration were prominent symptoms: the fourth patient suffered from attacks of dyspnœa, whilst one of the others had attacks of palpitation and præcordial distress. Three suffered from severe headaches and all were constipated. In all it is noted that the conjunctivæ were injected and in two bleeding occurred from the gums. The liver was slightly enlarged in three of the cases, but jaundice only existed in the one which I have reported, though in another there was once a trace of bile in the urine. The spleen was markedly enlarged in three of the cases and in all four there was a trace of albumin in the urine with a few hyaline casts. Patches of pigment were noted in one other case besides my own. The condition of the blood was practically identical in all four cases; there was a great increase in the number of red corpuscles, which often amounted to more than double the usual number. The hæmoglobin was always markedly increased, but by no means proportionately to the number of the red cells. The white corpuscles were either normal or but slightly increased. All the patients were over 45 years of age.

It is impossible to make any suggestion as to the pathology of these cases in the absence of more detailed anatomical observation. Dr. Cabot was unable to obtain any but the most meagre information of the necropsy on his case, and two of the other three patients were still alive when the reports were published. In the case which I have recorded there was no microscopical examination of the bone-marrow or the suprarenals, and the condition of the thymus was not noted. M. Weil[1] has recently recorded two cases of congenital cyanosis in children, apparently without heart lesion, but with "*hyperglobulie*" and, in one case, enlargement of the spleen, in which there were marked changes in the bone marrow and thymus. A careful examination of the suprarenals is suggested by the extreme muscular feebleness which, apart from the cyanosis, was the leading clinical feature of my case

I am indebted to Dr. Saundby for permission to publish the notes of the case.

## PATHOLOGICAL SOCIETY OF LONDON.

### *The Reactions of the Bone-marrow and other Leucocyte-forming Tissues in Infections.*

A MEETING of this society was held on Feb. 18th, Mr. W. WATSON CHEYNE, the President, being in the chair.

Professor R. MUIR (Glasgow) made a communication, illustrated by lantern and microscopical demonstrations, on the Reactions of the Bone-marrow and other Leucocyte-forming Tissues in Infections. He pointed out the difference in distribution of the functional activities of the leucocytes—the germ centres of lymphoid tissue, Malpighian bodies, &c., and the bone-marrow being essentially formative areas and the lymph sinuses and splenic pulp being specially adapted for phagocytic activity, &c. The bone-marrow was the seat of formation of the characteristic elements of the blood—red corpuscles and granular leucocytes. He had shown by experiments that this activity as regarded neutrophile leucocytes was greatly increased in inflammatory and suppurative conditions. An account was given of observations in like states in the human subject, a great many different conditions being investigated. The results were entirely confirmatory, the leucoblastic change (neutrophile reaction) being shown not only by an increase of the myelocytes in the existing marrow, but by a partial change of the fatty marrow into red marrow. At the spreading margin of the young marrow the chief elements found were red corpuscles and neutrophile myelocytes, there being no evidence that the latter were formed from non-granular cells. The newly formed marrow ultimately contained all the elements of the normal marrow, the distinctive feature being the relative excess of the neutrophile cells. Mitotic division was most active in these latter. In addition to the marrow obtained post mortem the condition of that obtained during life in cases of rib-resection for empyema was described. The state of the marrow in small-pox was then considered. In this disease there was always a percentage diminution of neutrophiles, though the actual number might be somewhat increased; the lymphocytes and hyaline cells showed both a relation and absolute increase, the percentage being sometimes as high as 60. The marrow showed very slight or no neutrophile reaction (a slight extension in the femur was often present) and there was often, especially in grave cases, a great depletion of its cells, notably neutrophile myelocytes, the place of them being taken by widened vascular channels distended with blood. The presence of these cells in the blood and the spleen was related to this change. These changes were the result of toxic action. The gelatinous change in the marrow was next considered, this affecting both the fatty marrow and the red marrow. Evidence was given to show that the essential factor in its production was starvation. It might be associated with leucoblastic change, though probably tending to interfere with the latter. The conditions governing the chief variations of the neutrophile cells in the tissues, the blood, and the marrow had been established; in all probability the eosinophiles behaved in an exactly analogous manner. The chief pathological changes in the bone-marrow were the following. 1. Changes in leucocythæmia—lymphatic and medullary respectively. 2. Reactive changes: (*a*) leucoblastic—the neutrophile reaction, in all probability also an eosinophile reaction, and possibly a hyaline reaction; and (*b*) erythroblastic—normoblastic after hæmorrhage, megaloblastic in pernicious anæmia, also in bothriocephalus anæmia. 3. Degenerative or retrogressive changes: (*a*) gelatinous marrow; and (*b*) fatty marrow, recorded in a case of idiopathic anæmia, possibly aplastic. The spleen was chiefly treated of in contrast to the bone-marrow, the outstanding feature being the extensive destructive changes in the former as contrasted with the formative functions of the latter. Acute enlargement was chiefly due to accumulation of blood or of leucocytes, hence variation in the colour. Both endothelial cells and hyaline cells might increase in number and size and act as phagocytes. In addition to bacteria, damaged red corpuscles and neutrophile leucocytes underwent an intra-cellular destruction by non-granular phagocytes (to a greater extent in animals than in the human subject); they were also digested extra-cellularly. Myelocytes appeared in the pulp, especially in severe cases, and with them nucleated red corpuscles were usually present. They probably represented an escape from the marrow owing to disturbance of its delicate structural arrangements. Proliferative changes occurred at the periphery of the Malpighian bodies, a zone of comparatively large basophile cells resulting (the potential myelocytes of Dominici, Bezançon, &c). In the neighbourhood of these myelocytes might be seen, but it was not certain that the latter were formed from the basophile cells. The marrow elements present might merely be separated from the blood; the question of "myeloid transformation" must be considered an open one. With regard to lymphatic glands and other lymphoid tissues, evidence that an increased formative activity could be produced by substances in the blood was still wanting. In small-pox there was a lymphocytosis in the blood, but this might possibly be due to irritating substances carried by the lymphatics from the skin lesions, &c. Local hyperplasia of lymphoid tissue might be produced by abnormal conditions in the corresponding area drained through it. Enlargement of glands in infections was, however, usually due to one of two causes. The first was the emigration of neutrophile leucocytes from the blood-vessels (as in other tissues); these might invade the whole gland structure. In milder cases with favourable results these cells might be destroyed by the non-granular phagocytes and a return to normal follow. The other cause was the reaction in the lymph sinuses and paths—marked desquamation and proliferation of endothelial cells with phagocytic activity occurred. This was seen well in typhoid fever and also in a somewhat similar manner in small-pox, especially with extensive skin lesion. A study of the lymphatic glands in infections afforded no evidence whatever that organs it was too late to apply x-ray treatment to the original site of the disease. Dr. LEWIS JONES concluded by explaining that the scope and aim of the British Electro-therapeutic Society were mutual instruction by bringing forward reports of work done and scientific examination of that work. Uniformity in apparatus was to be brought about and they must be prepared to inform scientific men as to the instruments which they could usefully employ in investigations. The journal of the society must be the medium for putting all their members in touch with what was being done, both at home and abroad. The encroachment of unqualified persons upon the field of work of the society was a very serious matter which should engage the attention of all the members. In some instances medical men had too thoughtlessly countenanced this practice and it was only too late that the medical men discovered the loss which they sustained and were sustaining. The taking of x-ray photographs by photographers and instrument-makers was undoubtedly a bad thing for the profession. The treatment of lupus by any irresponsible person who happened to have an induction-coil should not be countenanced by any medical man, and with the possibility of the use of the x rays in the treatment of cancer the danger became greater. He had been told already of a fatal case where a patient suffering from cancer died from the effects of the x-ray treatment applied by an unqualified person.

Dr. G. HERSCHELL, Dr. S. SLOAN, and Mr. J F. HALL-EDWARDS (Birmingham) exhibited Apparatus, and Mr. E. W. H. SHENTON showed Radiograms illustrating Certain Points in Hip-joint Injuries.

## LIVERPOOL MEDICAL INSTITUTION.

*Cerebellar Abscess with Thrombosis of the Lateral Sinus.—Exhibition of Cases.—The Preparation of the Hands for Surgical Operations.*

A MEETING of this society was held on Feb. 13th, Mr. USHTON PARKER, the President, being in the chair.

Mr. DAMER HARRISSON described a case of Cerebellar Abscess with Thrombosis of the Lateral Sinus in a young man who had suffered from ear disease for 11 years. There were some dulness of the intellectual faculties, paresis of the right facial nerve, and a tendency to fall to the right side. There were also some swelling over the mastoid process and fulness in the upper part of the neck. There was no optic neuritis. The antrum was cleared, the necrosed inner wall was removed, and the abscess cavity was opened up. The patient became very collapsed and further operation was deferred. After a few days, the temperature being still irregular, the internal jugular vein was exposed and ligatured below the thrombus, an excised bit of vein contained a softening clot. The patient made an excellent recovery.—Mr. C. G. LEE had seen some 30 cases of cerebral and cerebellar abscess resulting from ear disease. In many cases it was often impossible to say in which situation the abscess was. Optic neuritis was as frequently absent as present in cases of cerebral and cerebellar abscess. Cerebral abscesses were frequently multiple, and he referred to the case of a child who had paralysis of one arm and leg in which he opened and evacuated the abscess. This was followed by complete recovery of the limbs. Ten days later the child died, and the post-mortem examination showed the whole of one occipital lobe necrosed and several small abscesses scattered about the cerebrum.—Dr. PHILIP NELSON asked if the source of the discharge from the ear had been definitely ascertained, for owing to difficulty of drainage mastoid and other complications were more liable o occur when the attic was the seat of the trouble, the erforation being in the membrana flaccida. Referring to the acial palsy, he pointed out the frequency of this trouble in tuberculous disease, particularly in children.—The PRESIDENT, Dr. W. PERMEWAN, Dr. A. S. F. GRUNBAUM, and Mr. R. W. MURRAY spoke, and Mr. HARRISSON replied.

Dr. NATHAN RAW showed a woman upon whom he had performed Cæsarean section twice. There was no evidence of rickets. The conjugate diameter of the pelvis was two and one-third inches, the promontory of the sacrum projecting markedly. At the time of the first section the patient had been 26 hours in labour and general cutaneous emphysema was present. The child from the second section was shown and attention was drawn to the circular shape of the head. Dr. RAW raised the question as to what the correct procedure was in this case. The patient was unmarried. He thought that she must take the consequences but it was a most difficult question to answer.—The PRESIDENT, Dr. W. MCFIE CAMPBELL, Dr. H. BRIGGS, Mr. F. T. PAUL, Mr. HARRISSON, and Mr. G. P. NEWBOLT spoke, and Dr. RAW replied.

Dr. DAVID MORGAN showed three cases of very obstinate and extensive Lupus and Rodent Ulcer cured by the x rays and violet light. The first patient, a woman, aged 34 years, had suffered from childhood from lupus of the nose and cheeks. Every variety of surgical treatment had been adopted, including over 40 scrapings, but the benefit was only temporary. X ray treatment had proved quite successful, the patient exhibiting a very healthy white scar. The second case was that of a tuberculous ulcer of the cheek of limited size treated by the violet rays. A healthy cicatrix formed in six weeks. In the third case a large rodent ulcer presented over the scalp and forehead in an elderly spinster. The disease had been in progress for many years and was too extensive for excision. Three months' treatment with x rays had cured the disease.—Dr. FRANK H. BARENDT thought that the results produced by the x rays and light treatment in Dr. Morgan's three cases had been unattained by any method hitherto practised. The case of healed serpiginous rodent ulcer of 12 years' duration showed an excellent result. No previous treatment had any permanent effect, and now the former site of the ulcer was occupied by a smooth and to the naked eye sound scar; moreover, there was a total absence of any return. The dermic results of the x-ray and light treatment could not at present be explained; it was futile to theorise about these therapeutic effects in the absence of definite knowledge of the nature of the rays which had produced such remarkable results as were portrayed in these cases.—Dr. G. G. STOPFORD TAYLOR congratulated Dr. Morgan upon his interesting and instructive demonstration. He said that the effect of the "light" treatment was largely superficial, and the number of cases to which it could be applied were limited in number on account of the necessity of actually placing the lamp in contact with the surface. With the x rays it was quite a different matter as they certainly penetrated much more deeply and could be therapeutically applied to every part of the body.—Mr. ARTHUR N. WALKER mentioned that Dr. Finsen had found Bang's iron electrode lamp unsuccessful in the treatment of lupus on account of the lack of penetration of its rays.—The PRESIDENT and Mr. PAUL emphasised the need for microscopical confirmation of the diagnosis.—Dr. PERMEWAN and Mr. C. T. HOLLAND also spoke and Dr. MORGAN replied.

Dr. T. B. GRIMSDALE described the method which he had used for some time in the Preparation of the Hands for Surgical Operations. The hands were cleaned with a nail-brush and boiled water for a definite time, then they were soaked in a solution of potassium permanganate, the colour was discharged by washing in oxalic acid solution, the acid neutralised by washing in sterilised lime water, and, finally, the hands were washed in sterilised water. The results of this method had been rigorously tested on several occasions by Dr. E. E. Glynn, Dr. J. H. Abram, and Dr. C. Hill. In every instance Dr. Grimsdale's hands and those of his assistants were sterile, and his opinion, therefore, was that the hands could be made practically sterile. Moreover, of all the methods that he had tried this one had the least roughening action on his skin—in fact, it did not roughen it at all. He did not think that the method was simply mechanical in its action.—The PRESIDENT, Dr. BRIGGS, Dr. HILL, Dr. GRUNBAUM, Mr. HARRISSON, Mr. PAUL, and Mr. G. A. HAWKINS-AMBLER discussed the paper, and Dr. GRIMSDALE replied.

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

(*Concluded from p. 453.*)

*Chloroma and Lymphatic Leukæmia.—Infantilism.*

WE now conclude our report of the fifth ordinary meeting of the present session of this society, held on Feb. 5th, Professor T. R. FRASER, the President, being in the chair.

Dr. BYROM BRAMWELL read notes of a case of Chloroma and of three cases of Lymphatic Leukæmia, illustrated with water-coloured drawings and lantern-slides. In the first of these cases the patient was a married man, aged 25 years, acute stage. With regard to his own and Dr. Sainsbury's cases at the Royal Free Hospital, he said that during the last five years they had had 53 cases. 49 of the patients in these cases got well, four died, a mortality of one in 13. 34 of these had been admitted to the surgical ward and of these three had died, a mortality of one in 11. Of the patients in those three cases in which death occurred one was an old man, aged 51 years, who had general peritonitis and had been ill for four days when first seen; a second was a boy who died from intestinal obstruction; and the third was a case in which if operation had been performed early the fatal termination might have been prevented. He asked if Mr. Barling attached any importance to the presence of a low temperature, as he had seen such cases and they seemed to him comparable to those cases of low temperature in association with abscess in the brain.—Mr. CUTHBERT S. WALLACE said that he had met with three cases of recurrent abscess after appendicitis. The first was a woman, aged 53 years, who four months after the primary operation had an abscess in the same situation, and after incision the patient again recovered. The second was in a man in whom an abscess recurred four months after the first operation. The appendix was removed at the second operation, but the patient died on the twelfth day. The third was in a man who had a recurrence two and a half months after the first operation. In the St. Thomas's Hospital Reports from January, 1895, to December, 1901, there were eight cases of recurrent appendix abscess. One of these occurred three weeks after the first abscess had been opened; in the remainder the interval between dates of admission and re-admission was from two to four months, except in two cases in which the interval was 19 months and seven years respectively. During this period 128 localised appendix abscesses had been incised, making a recurrence frequency of 5·5 per cent.—Mr W. G. SPENCER said that he should always open an appendix abscess as soon as he had diagnosed the presence of pus. He considered that the iliac incision was far better than one opening the general peritoneal cavity, as it was easier to find the appendix, or if not found at once it could be traced from the cæcum. He criticised Mr. Berry's statistics in respect of the comparative mortality between medical and surgical cases and thought that they did not fully represent the facts, as in many cases the patients died before they came to operation, and therefore would not be included in his figures. [Mr. BERRY denied that he had instituted any such comparison.] He asked Mr. Barling if the patients in his cases had remained in good health after the operation, for he thought that although these patients did not have recurrence they yet frequently suffered from general ill-health. He considered it advisable to remove the appendix at the time of the first operation. He had employed a method of secondary suture in two cases where the abscess had been large. He incised the abscess, packed the cavity with gauze, and after a week, when granulations had formed, he sewed up the cavity.—Mr. C. R. B KEETLEY said that he was inclined to remove the appendix in as great a proportion of cases as possible and he considered that by using gauze packing in a systematic manner this could be done without increasing the risk. He thought that it was best to open the abdomen in the mid-line, for in this way a view of the condition present could be obtained. He considered that it was rare to meet with multiple collections of pus.—Mr. CHARTERS J. SYMONDS thought that it was much better not to remove the appendix in most cases. He considered it better to make an incision nearer to the anterior superior spine than over the most prominent part of the swelling, for in this way one was less likely to open the general peritoneal cavity. In considering the dangers which attended the non-removal of the appendix he said they were two: *firstly, the possibility of recurrence* (and of these he had seen two cases both discharged through the old scar); and secondly, the possibility of the formation of a sinus. Neither of these did he consider of serious consequence. He was in favour of immediate operation and he did not think that he had ever seen any harm follow such practice. If the general peritoneal cavity was opened he thought it best to pack the cavity and to open the abscess. If the swelling was found to be in the lumbar region it was best to close the abdominal opening and to open the abscess in the loin. If the swelling was in the pelvis he recommended that the abscess should be opened into the rectum.—Sir THOMAS SMITH said that he considered that the incision should be made low down; if it were made over the most prominent part of the swelling there was considerable chance of opening the general peritoneal cavity. If he failed to obtain pus after making the low incision he was in the habit of putting in a drainage-tube and he had often seen the pus come through this after a few days.—Dr. H. A. CALEY stated that the proportion of relapses in cases which had been operated on was certainly not more than from 1·5 to 2 per cent. and that 5 per cent. was too high. He asked if a counter opening in the lumbar region might not be of value in some cases.—Mr. BARLING, in reply, said that the general consensus of opinion of the society had been that the appendix should not be removed unless this could be done with ease. He could not agree with Mr. Berry with regard to waiting, but would always operate at once.

# BRITISH ELECTRO-THERAPEUTIC SOCIETY.

*The Present and Future of Electro-therapeutics.*

A MEETING of this society was held on Feb. 14th, Dr. W. S. HEDLEY, the President, being in the chair.

Dr. H. LEWIS JONES read a paper on the Present and Future of Electro-therapeutics. The changes in the practice of medical electricity which had taken place in the last 12 years were numerous. The general introduction of public electric lighting supplies had not only helped greatly to extend the practice of medical electricity, but had also provided the profession with a new and valuable agent in the sinusoidal current. In electrical testing there was still need for a method of measuring induction-coil currents, and the difficulties of doing this might be evaded by the substitution of condenser discharges in place of them. Galvanometers and electrodes were much improved. The brass handles and the wet sponges were, or ought to be, things of the past. Chemical batteries, with the troublesome preparation of exciting fluids, were being rapidly discarded by the profession and the modern dry battery or the portable accumulator was superseding them, with the result of greater simplicity in working and greater confidence in the instruments used. The static machine had begun to return to favour and seemed likely to achieve great things in the near future. The treatment of lupus and of rodent ulcer by electrical methods seemed to be assuming an established position. In a case of ulcerated cancer of the breast under treatment at St. Bartholomew's Hospital there had been extensive healing from exposures to x rays. The patient when admitted had a large open ulcerated wound of the right breast, measuring about four inches in one diameter and five inches in the other. Treatment with x rays was commenced on Nov. 14th and an exposure of 10 minutes was given four times a week, with few omissions, until Jan. 17th. After a few days signs of healthy cicatrisation began to appear round the margins of the ulcer. This continued to advance until the healing process had extended inwards from the margin for a distance of fully half an inch all round. Curiously, the new epithelium was deeply pigmented. The centre of the wound gradually ceased to slough and appeared to be in process of healing all over; but, unfortunately, the patient being at a late stage of her illness, secondary deposits in remote parts of the body became very disagreeably evident. She suffered a spontaneous fracture of both the femur and the humerus, and the x-ray treatment was suspended in view of the hopelessness of the future of the patient. The total number of exposures was 17, and it was very important to note that many were made with the ulcerated surface covered by dressings or bandages. Since the suspension of the treatment exactly four weeks ago, the process of healing had gone on quite steadily, and now there was a firm and healthy scar covering the whole surface, except about one square inch in the centre. This portion was also a healthy healing surface, though not yet covered by epithelium. Thus nineteen-twentieths of the area of a cancerous ulcer had healed in three months as a consequence of x ray applications, and the result was obviously a most significant one. The local effect was splendid, but there was no influence upon the spread of the disease in the remote parts of the body. Indeed, it would have been unreasonable to expect it. The opportunity must be hoped for of treating some cases of cancer in the early stage when the disease was still limited to the superficial part, for when the disease was no longer local but had implicated distant and deep-seated

Professor George Dock, who had made a special study of the disease. Professor Dock agreed with him in thinking that the first case which he (Dr. Bramwell) had described was a case of chloroma. As Dr. Dunlop had told them, chloroma was a very rare disease, some 25 cases only having been recorded up to the present time. In typical cases the characteristic features of chloroma were as follows. 1. The presence of lymphoid deposits in the orbits, temporal fossæ, and periosteum of the bones of the skull, and the symptoms and signs resulting therefrom. In consequence of the lymphoid deposits in the orbits there was usually, but not always, exophthalmos ; and often as the result, partly, perhaps, of the pressure on the optic nerve and its vaginal sheath, and partly of the altered blood condition (lymphatic leukæmia and anæmia), hæmorrhages in the retinæ and optic neuritis. Lymphoid infiltrations of the conjunctivæ, which in some cases produced large protruding swellings giving the idea of sarcomatous growths, sometimes occurred. Lymphoid infiltrations of the cornea were also sometimes developed. Firm bilateral swellings in the temporal fossæ were very often present. The periosteal lesions were not confined to, though they were apparently always most marked in, the region of the skull and face. The periosteum of the bones of the vertebral column was often affected. In a recent case (Rosenblath's first case) the spinal column was eroded, the nerve roots and spinal cord were pressed upon, and secondary ascending degeneration in the spinal cord developed. Deafness was very common; it was apparently in some cases due to pressure on the auditory nerve, in others to lesions (involvement) of the middle or internal ear. Facial paralysis, due to pressure on the facial nerve, was sometimes met with. There was in many cases difficulty in breathing through the nose, the result of swelling and infiltration of the nasal passages. The tonsils were often enlarged and infiltrated. The remarkable swelling of the gums, epiglottis, and larynx, which was present in the two cases which he had related, had not, so far as he had been able to find, been hitherto described, but he was much interested to find, when Dr. Dunlop kindly gave him an opportunity of seeing his case during life, that in his case the palate was swollen and infiltrated in exactly the same manner. 2. The green colour of the lesions (lymphoid deposits in the orbits, periosteal lesions, lymphoid deposits in the kidneys, the liver, the spleen, the bone-marrow, &c.). This was a remarkable feature of the disease. In many cases the green discolouration was only noticed after death. But that the green colour, in some cases at least, was not due to post-mortem changes was conclusively shown by the fact that in some of the recorded cases the urine was green during life. As Dr. Dunlop had stated, the exact cause of the green colour was still unknown. In his own case the change in colour which the skin lesions went through during life was suggestive of a blood change, and the marked increase of the green colour which was noticed at the post-mortem examination in the skin lesions in the upper part of the body seemed to be suggestive, in part at least, of a post-mortem (? decomposition) change. The question naturally arose whether in all cases of chloroma the green colour was due to the same cause. It was possible that it might be due to different causes in different cases and that the green tumours were not invariably due to one and the same pathological condition. Further, though this might at first sight seem to be a contradiction in terms, it seemed to him probable that cases of chloroma occurred in which there were no green tumours and no green lesions. He was strongly disposed to think that the green discolourations, though they had hitherto been considered to be essential and characteristic features of the disease, might in some undoubted cases of chloroma be absent. These questions required solution. 3. A profound blood change, characterised by anæmia, cachexia, hæmorrhages into the skin, bleedings from the mucous membranes, especially epistaxis, and petechial extravasations into the retinæ and internal surfaces (epicardium, &c.). The same profound blood change was met with in most cases of acute lymphatic leukæmia, but it was certainly not always present. In the first two cases which he had just described (of chloroma and acute lymphatic leukæmia) there was little or no anæmia and there was no cachexia. The essential blood change in chloroma seemed to be an enormous excess of the lymphocytes and especially of the large lymphocytes in the blood ; in short, in cases of chloroma the blood seemed (? always) to present the characteristic features (95 per cent. or more of lymphocytes) which up to the present time were regarded as indicative of one condition only—viz., lymphatic leukæmia. 4. Further, the bone marrow, the spleen, the lymphatic glands, and the organs throughout the body were affected (infiltrated with lymphoid deposits) as in lymphatic leukæmia. In all the recent cases of chloroma which had been examined exhaustively the blood presented the characters of lymphatic leukæmia. In some cases in which it was said that there was no excess of leucocytes the character of the corpuscles *had not been ascertained by stained films.* Now, the first case which he had related showed that lymphatic leukæmia might be present when there was no excess of leucocytes. The question whether chloroma was a definite and distinct disease or whether it was merely a variety of acute lymphatic leukæmia was a very difficult one to answer—a good deal could be said on both sides. The peculiar location of the lesions to the orbits and skull bones, though they were not of course confined to these parts ; the green colour of the tumours ; the fact that in some cases the tumours were of cartilaginous consistency ; and the fact that in some cases the bones (as in one of Rosenblath's recent cases) were eroded and perforated by the growths, were in favour of sarcoma or lympho-sarcoma rather than of lymphatic leukæmia. But the condition of the blood was highly suggestive of lymphatic leukæmia. The three cases which had been brought before the society that evening seemed to show that no hard-and-fast line could be drawn between acute lymphatic leukæmia and chloroma. Dr. Dunlop's case was a highly typical case of chloroma with all the changes in the blood characteristic of acute lymphatic leukæmia. The case now being considered was a typical case of very acute lymphatic leukæmia with peculiar lesions in the gums, the tonsils, the larynx, and the skin, and the first case seemed to be midway between the two—between Dr. Dunlop's case and Dr. Bramwell's second case. The mouth lesions appeared to be the same in all three cases. The whole question seemed to turn upon the nature and definition of lymphatic leukæmia. Possibly the same condition of blood (95 per cent. or more of the white corpuscles being lymphocytes) might result from more than one pathological condition. But, practically speaking, lymphatic leukæmia and chloroma were the only known diseases in which such a condition of blood was present. Probably more than one disease was included under the term "acute lymphatic leukæmia," or, at all events, different varieties of the disease existed. Certainly different cases of lymphatic leukæmia presented considerable differences in their clinical history and course and in the relative intensity of the lesions found after death in the bone-marrow, the spleen, and the lymphatic glands respectively. In this connexion Dr. Bramwell next briefly described his third case—a case of very acute lymphatic leukæmia which had just occurred in his hospital practice, in which there was comparatively little glandular change, but in which the lesions in the spleen and in the bone-marrow were very marked ; this case was very interesting because of a peculiar condition of the kidneys. Both kidneys were very much enlarged and the cortical substance was infiltrated with numerous large hæmorrhages, the intervening substances being pale, exactly of the colour of very anæmic brain tissue; the left kidney weighed 18 ounces and the right kidney weighed 14 ounces. The peculiarity of the condition was that the urine, which was carefully examined on three separate occasions during the last three days of life, was pale and was absolutely free from blood and albumin. At the post-mortem examination the bladder contained 14 ounces of very pale urine, the specific gravity of which was 1012 ; it was absolutely free from blood and it contained the merest trace of albumin which was perhaps derived from the vesical epithelium. Dr. Bramwell next referred to a case—the fourth case—one of chronic lymphatic leukæmia in which there were enormous glandular swellings throughout the body. Lantern slides illustrative of the condition of the blood, &c., in these cases were shown. In conclusion, Dr. Bramwell stated that the present communication was merely preliminary. It had been impossible in the time placed at his disposal to attempt to discuss the questions exhaustively ; all he had attempted to do was to mention the chief clinical and pathological facts of the cases which he had related.

Dr. **Bramwell** also showed a case of Infantilism. The condition was very rare and, so far as he had been able to ascertain, was not described, though incidentally referred to, in medical literature. The patient, aged 18 years and 10 months, did not look more than 12 years of age. He was bright and intelligent mentally. There was no suspicion of who had enjoyed excellent health up to October, 1900, when he accidentally discovered a small glandular swelling on the left side of the neck below the jaw; a week later a similar swelling developed on the right side of the neck. In January, 1901, an eruption developed on the front of the chest and gradually extended over the greater part of the body. In February rheumatic pains were felt for a fortnight in the back. In April the face and gums swelled, the eyes became watery and painful and the voice husky, and some deafness developed. On May 22nd, 1901, the patient was sent to Dr. Bramwell by Dr. C. E. Douglas of Cupar. The condition was then as follows. The patient was much debilitated and had lost a stone in weight. He complained of soreness of the mouth and gums and of deafness, more marked in the right than in the left ear. He was not anæmic. There was no excess of white corpuscles in the blood. The face was swollen, the swelling being chiefly due to the presence of nodular swellings in the skin, œdema of the skin, and glandular swellings in the neck and parotid regions. The voice was husky, the breathing was attended with some stridor, there was frequent cough, and the patient could not breathe through the nose. The pulse was quick (from 120 to 130) and the temperature was 100·6° F. A remarkable eruption was present over the greater part of the body; it was copious on the thorax, the abdomen, the back, the arms, the face, and the scalp, but sparse over the lower extremities. The eruption consisted of flat-topped nodules varying in size from that of a pin's head to that of a sixpenny-piece. In many places the nodules were confluent and they produced a uniform raised infiltration of the skin; they were painless, not adherent to the deeper parts, and for the most part of a slatey-grey or purple-grey colour, some of them being yellow in their centres. The gums were enormously swollen, firm, and of a dark purple colour, and the right tonsil was much swollen and was also firm and of a dark purple colour. The conjunctivæ presented a peculiar appearance, being infiltrated with a translucent fleshy-looking growth in which vessels could be seen ramifying. There was no exophthalmos. The optic discs were normal. The glands on each side of the neck below the jaw were swollen, hard, and painless. The parotid glands appeared to be enlarged. There was some symmetrical swelling in each temporal region. The splenic dulness was increased. The liver was somewhat enlarged. The urine was normal. There were no pigmented moles or warts, but Dr. Bramwell concluded that the case was probably one of melanotic sarcoma, with peculiar infiltration of the skin, the gums, the tonsil, and the conjunctivæ. The patient was admitted to the Edinburgh Royal Infirmary on May 23rd and he remained there until his death, which took place a month later—on June 24th. Microscopical examination of portions of skin excised during life showed that the case was not one of melanotic sarcoma; the nodules in the skin consisted of lymphoid deposits and were entirely made up of small unenucleated round cells. The blood-count showed that the red corpuscles numbered 4,480,000 and the white corpuscles 8000 per cubic millimetre. The white corpuscles were almost entirely (95 per cent. or more) lymphocytes, chiefly large lymphocytes, with large nuclei and clear, non-granular protoplasm. During the month that the patient remained in hospital the condition of the blood remained practically the same. The temperature was elevated, the highest point reached being 104°, and the pulse was remarkably quick (from 110 to 160); the respirations were always above the normal (from 25 to 35). The breath was foul and the gums occasionally bled slightly. No micro-organisms were detected (either in stained films or after incubation of gelatin tubes) in the blood The skin eruption increased and many of the nodules became yellow, some yellowish-green, and a few on the face distinctly green in colour. The face became much more swollen The fleshy infiltrations of the conjunctivæ became much larger. On post-mortem examination the skin lesions (nodules) on the face, the thorax, the abdomen, the back, and the arms were of a green colour; some of the glands in the neck were green, the tonsil was green, and the epiglottis and laryngeal mucous membrane were green. The bones of the head and face were not examined (permission was limited to the respiratory and abdominal cavities). The glands in the neck were enlarged, the spleen and the liver were enlarged, and the gums, the tonsils, the epiglottis, and the larynx were greatly swollen, the swelling being due to lymphoid infiltration. The bone-marrow of the ribs contained some, but not very numerous, lymphoid cells similar to those in the skin, the gums, and the blood. There were some petechiæ on the heart. The thoracic, the abdominal, the axillary, and the inguinal glands were hardly affected at all. The kidneys were infiltrated in places with lymphoid deposits. The case was undoubtedly one of chloroma. The condition of the blood corresponded to that of acute lymphatic leukæmia and it was very important to note that the leucocytes (95 per cent. or more of which were lymphocytes) were not increased in number (8000 per cubic millimetre). The mere fact that the leucocytes were not increased in number did not exclude leukæmia. It was necessary to note the character of the leucocytes in stained films. The case was remarkable because of the lesions on the skin and the very peculiar infiltration of the conjunctivæ, the gums, the epiglottis, and the larynx. Dr. Bramwell had never seen anything like the condition of these parts before. Curiously enough, another case in which exactly similar lesions were present had since come under his observation. The second of Dr. Bramwell's cases was one of acute lymphatic leukæmia with a similar lesion in the gums, the epiglottis, and the larynx to that which was present in the first case. The patient was a man, aged 33 years, who was admitted to the Edinburgh Royal Infirmary on Sept. 29th, 1901, and who died on the following day. He complained of shortness of breath on exertion, of deafness, and of glandular swellings on each side of the neck and the jaw. The deafness had commenced a month previously, but he had continued his work until three days before his admission to the hospital. He was a thick-set, well-nourished, muscular man. There was no anæmia—in fact, his face and lips were turgid and cyanotic. No examination of the blood was made during life, but after death the blood was found to contain a large excess of lymphocytes, mostly of the large form. The patient was very deaf. His voice was husky and almost toneless, he was very short of breath, and the respiration was attended with stridor. Large, hard, painless, glandular swellings were present on each side of the neck, being especially marked about the angle of the jaw, the face was swollen and blue, and the veins of the neck were somewhat engorged. Dr. Bramwell, who had seen the patient for a moment on his admission to hospital but had not made an exhaustive examination of the case, thought that the condition was suggestive of enlargement of the mediastinal glands with intra-thoracic pressure. The case had been more carefully examined by Dr. Montgomery Bell, house physician. The chest was full of bronchitic râles. The pulse numbered 108, the temperature was 102°, and the resiprations were 20. The tonsils were swollen and ulcerated. The patient died on the day following his admission to hospital. Post-mortem examination showed that the case was one of acute lymphatic leukæmia. The glands throughout the body were enlarged; the spleen, liver, and kidneys were infiltrated throughout with lymphoid cells; and the bone marrow was of a dark purple colour and was infiltrated with lymphoid cells. In the skin of the back and neck there were several lymphoid deposits similar to those which were present in the first case and the condition of the gums, the tonsils, the epiglottis, and the larynx was also identical with that in the first case. Some of the glands in the neck in the case under consideration were found on section to be green in colour. This case was undoubtedly a typical example of very acute lymphatic leukæmia with peculiar lymphoid infiltrations of the gums, the tonsils, the epiglottis, and, to a very limited extent, the skin. The two cases when taken together had, Dr. Bramwell thought, an important bearing upon the pathology of chloroma. That disease was very rare, but it was probably much more common than was usually supposed. Many cases were no doubt missed. A case figured in the *Medical Review of Reviews* for November, 1901, p. 695, and described as a "rapidly-growing tumour of the orbit," was, Dr. Bramwell had no doubt, a case of chloroma. Some years ago a friend in Barbadoes had sent him a photograph of a remarkable case of symmetrical sarcomatous growths of the orbits with exophthalmos which was probably a case of chloroma; it appeared to be merely an exaggeration of a case of chloroma recently published by Rosenblath.[1] It was probable that some of the rare cases of so-termed perforating sarcoma of the skull, of which he had reported a case a few years ago, were cases of chloroma. He had had the advantage in August last of discussing the whole subject of chloroma with

---

[1] Deutsches Archiv für Klinische Medicin, Band lxxii., Heft 1, 1902.

Sternalis was found in Anencephalous Fœtuses. Throughout Europe it awakened interest, and by that single paper the section at once became an object of interest to anatomists. Discussions throughout the medical schools of the world took place on the subject and the views of the Dublin school were opposed strongly; but he was glad to say that the two papers of Eisler of Berlin and of Wilson of Melbourne supported the views put forward by Mr. Abraham. The cerebral wave was created by the remarkably beautiful exhibition of cerebral photographs prepared by Professor Alexander Fraser. For their general usefulness and beauty of finish they had never been excelled. Professor Fraser had also been engaged on the study of the topography of the sinuses of the cranium and under his hands the cerebral wave attained its highest point. The visceral wave included the splendid work done by Professor J. Symington of Belfast, and that of Professor Fraser, Professor A. Birmingham, and others.

The PRESIDENT (the chair being temporarily occupied by Professor Symington) then read a paper on the Inferior Parietal Lobule. He said that it had become the practice of a considerable number of continental anatomists to form an opinion of the sex, race, intelligence, and capability of the individual from an examination of the inferior portion of the parietal lobe of the cerebrum. He could not accept these views, although they had been supported by Retzius, Guzsman, Hauseman, and Ruge, and, indeed, he had been driven to a diametrically opposite conclusion. In a series of brains specially prepared to show the development of this lobule from those of the fœtus to those of advanced life he could find no reason to suppose that the higher intellectual powers were associated with a larger and more complex gyrated lobule. Professor Cunningham exhibited a series of screen pictures of cerebra in support of his views.—Professor D. J. COFFEY said that he considered the President's demonstrations of the surface anatomy of the inferior parietal convolutions a most interesting supplement to Flechsig's work on the development of association fibres in the same area. How far such an area could be termed a place of intellectual operations in the brain depended very much upon the exact signification to be attached to the term intellectual. Intellect itself, he thought, was a question of capacities not necessarily associated with any area, but deriving the matter through which it manifested its activities from both the primary sense areas and the association centres alike. He thought that the so-called intellectual areas in reality had to do with the conscious functions which were intermediate, so to speak, between primary sense representations in the brain and the higher psychical capacities. The latter had no place representation whatever.—Professor FRASER said that the brain of a lunatic was quite as complicated as that of a mathematician.—Professor SYMINGTON said that, like the President, he was doubtful of the localisation of special intellectual ability in the inferior lobule of the parietal lobe.

Professor COFFEY read a paper on Microscopical Preparations of Certain Nerve-endings in the Auditory Tract. He demonstrated the three typical forms of endings of the cochlear nerve in the pons cerebri, calyces, tree-root endings, and encapsuling fibres. The specimens were stained after the manner of Cajal of Madrid and Wehl of Leipsic.—Professor FRASER and the PRESIDENT discussed the paper.

Professor BIRMINGHAM read a note on the "Stomach Chamber." About two years ago, in a paper contributed to the *Journal of Anatomy*, he introduced the terms "stomach chamber" and "stomach bed." In order to make plain to the section that there were a "stomach chamber" and a "stomach bed" he had brought a specimen hardened *in situ* by formalin and gelatin. The anterior abdominal wall having been removed, the stomach, which was distended and hardened and had been cut free at both extremities, was lifted out, showing a distinct chamber, bounded superiorly by the diaphragm and inferiorly by the small intestines, the pancreas, the upper extremity of the kidney, and the transverse mesocolon. The viscus when distended filled this chamber; when it was in a condition of contraction a portion of the colon pressed up in front of the viscus into the chamber. In the healthy male adult he found that the stomach projected downwards, at an angle of 45°, inwards and forwards. When distended its pyloric extremity tilted upwards and its œsophageal opening was not directly on its lesser curvature but opened on the anterior surface.—Professor SYMINGTON said that he quite agreed with Professor Birmingham that the stomach projected forwards and downwards, but he could not see any advantage in the term "stomach bed" or "stomach chamber."—The PRESIDENT agreed with Professor Birmingham that the titles "stomach bed" and "stomach chamber" were useful and helpful. The transverse mesocolon divided the abdominal cavity into a gastric and an intestinal region.

Dr. T. G. MOORHEAD read notes on the Abdominal and Pelvic Viscera in a case of Advanced Pregnancy. The specimen was hardened *in situ* by the formalin process and photographed. The subject had reached the seventh month of pregnancy, and it was probably the first occasion of such a specimen being photographed for exhibition. The uterus extended well up into the abdomen and inclined to the right side; the left ovary came in contact with the anterior abdominal wall. The uterus was also rotated on its long axis which brought the right ovary in contact with the cæcum. The upper margin of the uterus lay at a point two inches above the symphysis pubis and was overlapped by the transverse colon and the great omentum.—The PRESIDENT, Professor SYMINGTON, Professor FRASER, and Professor BIRMINGHAM congratulated Dr. Moorhead on his unique and splendid specimen.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Feb. 5th, Dr. Thomas Harris, the President, being in the chair.—Mr. F. A. Southam showed a female, aged 41 years, upon whom Cholecystectomy had been performed eight months previously. For four years she had suffered from attacks of biliary colic, unaccompanied by jaundice, and had frequently passed gall-stones in her motions. As the attacks were becoming very frequent and her health was beginning to suffer an exploratory operation was performed. The gall-bladder, which was found to be enlarged to the size of an orange, contained nearly four ounces of pus and 64 gall-stones. As its walls were thickened and indurated and the cystic duct was completely obliterated it was removed, together with a small portion of the liver substance, to which it was intimately adherent. The patient, who made a good recovery from the operation, had been free from any attacks of pain since its performance and was now in excellent health.—Mr. Southam also mentioned a case of Cholelithotomy where 260 calculi were removed from the gall-bladder of a male, aged 24 years, who had suffered from attacks of biliary colic, accompanied by jaundice, since he was 18 years of age. The patient made a rapid recovery from the operation.—Dr. H. Ashby brought forward a case of Gastro-enteritis in a boy, aged three years. There were persistent vomiting with rapid thready pulse and flattened abdomen, but there was no diarrhœa. Later there were "coffee-ground" vomiting and dark brown stools consisting of altered blood. There was no fever. There were convulsions and tetany before death, which took place on the sixth day. At the post-mortem examination a much-dilated stomach was found; the mucous membrane was markedly injected. The intestines were contracted and intensely hyperæmic, especially about Peyer's patches. The origin was obscure; irritant poisoning and milk- and meat-poisoning could be excluded with fair certainty.—Mr. W. P. Montgomery made a communication on two cases of Epiplopexy (Morison's operation) for Ascites. In the first case, a woman, 50 years of age, had noticed an increasing enlargement of the abdomen for six months. She admitted to a considerable indulgence in beer and spirits. She had been tapped once two months previously. The second patient was a man, 26 years of age, who had suffered from ascites for three years and had been tapped over 40 times. He gave no well-marked history of alcoholism. The diagnosis was chronic peritonitis with cirrhosis. In each case the omentum was fixed in the parietal peritoneum on either side of an incision made in the right semilunar line. It was then tucked up between the liver and the diaphragm, and fixed by a suture to the liver itself. After eight months the first patient remained free from any recurrence of the ascites. The second required tapping less frequently than before operation. An analysis of 38 collected cases was given.—Dr. Yonge showed two patients on whom he had performed Thyrotomy for Malignant Disease of the Larynx six months and five months ago respectively. In neither case was there up to the time of their being exhibited any evidence of recurrence. In the one case an excellent voice had been sporadic cretinism, of congenital syphilis, rickets, or tubercle. The only apparent cause for the condition was chronic diarrhœa, which had lasted for nine years and which was perhaps due, Dr. Bramwell had suggested, to defective pancreatic secretion. Dr. D. Young, house physician, had by an elaborate investigation, the details of which were communicated to the meeting, proved that the pancreatic secretion was deficient. Under the administration of pancreatic extract the diarrhœa had lessened, the patient had gained half a stone in weight, and had grown nearly half an inch in the course of six weeks. These facts suggested that in this case the arrested bodily development was due to defective pancreatic secretion. The condition of the pancreatic secretion in future cases of infantilism for which there was no apparent cause should be carefully investigated.

# EDINBURGH OBSTETRICAL SOCIETY.

*Exhibition of Specimens.—Symphysiotomy in Practice.—Diagnostic Help in Gynæcology.*

A MEETING of this society was held on Feb. 12th, Dr. JAMES RITCHIE, the President, being in the chair.

Dr. D. BERRY HART showed (1) a large Fibroid removed by supra-vaginal hysterectomy; and (2) a specimen of Transverse Rupture of the Fundus Uteri in a Full-time Pregnancy (the woman was not in labour and the rupture seemed to have taken place spontaneously).

Dr. F. W. N. HAULTAIN showed (1) a Fibroid Uterus affected with Carcinoma of the Body, removed by abdominal operation; (2) a Uterus with Adeno-carcinoma of the Body, with microscopical section, removed by the vaginal route; (3) two Ectopic Gestation Sacs at the third and fourth month respectively, removed from the same patient at different times within a year (the first sac had ruptured and the second was entire); (4) a Uterus with large Calcified Fibromyoma; and (5) a microscopical section from a case of Primary Tuberculosis of the Cervix.

Dr. J. W. BALLANTYNE showed (1) a Cephalometer for ante-natal mensuration; and (2) a Fœtus with Exomphalos and Adhesion of a Hand to the Chest Wall.

Dr. J. HAIG FERGUSON showed a Fibroid Uterus removed during menstruation.

Dr. R. C. BUIST (Dundee) read a paper on Symphysiotomy in Practice. Histories were given of four women, aged from 20 to 25 years. One patient had three labours with the loss of the infants and at her fourth labour had her pelvis permanently enlarged by Frank's method; the fifth labour resulted in an easily managed delivery of large twins. The second patient was rachitic and symphysiotomy was performed at her first and third confinements after forceps alone had failed; the second labour was spontaneous and natural. The third patient had had three difficult labours previously, with one child alive with a permanently dented head; in her fourth confinement symphysiotomy was performed. In the fourth case the patient had her first and second labours at the seventh month; at her third labour symphysiotomy was carried out after forceps had failed. Of the five children born after the operation four were alive and one died during labour owing to delay in sending for medical assistance. The conjugate diagonals varied from 8 to 9·5 centimetres (3⅛ to 3¾ inches). In two cases femoral thrombosis occurred during the puerperium. One patient, owing to an accident after the operation, had incontinence of urine, but this was cured by subsequent operation. The delivery after the operation was helped by forceps and the Walcher position. In none of the cases was there any subsequent impairment of gait and all of the patients had been able to do their work at home and two were at their work in the jute-mill within six weeks and three months after the operation respectively. The method followed in the last four operations was the subcutaneous method described by Ayres. Dr. Buist made an incision in the vestibule and passed a director up the front of the symphysis to its upper border; withdrawing the director he inserted a probe-pointed bistoury and cut through the symphysis, beginning at the upper border. The tissues behind were watched and guarded by a sound in the urethra and the finger pressing through the anterior vaginal wall. Sometimes there was difficulty in locating the symphysis and occasionally the osseous surfaces were not straight. Considerable hæmorrhage might occur after the operation and this could be met by packing. The after-treatment was simpler after the subcutaneous than after the open method. The paper was discussed by the PRESIDENT, Dr. HART, and Dr. FERGUSON, and Dr. R. JARDINE and Dr. J. M. MUNRO KERR (Glasgow) gave their experience of the operation.

A paper on Some Remarks on Diagnostic Help in Gynæcology was sent by Professor FEHLING of Strasburg and was read by the Secretary. Owing to the success attending gynæcological operations many operators, especially the younger gynæcologists, attached no great value to a thorough diagnosis. While in many cases a definite diagnosis was not essential to a successful operation, there were many cases in which an accurate diagnosis might assist in the selection of the best operation or in modifying the steps of the procedure. Their aids in diagnosis had been constantly improving. The clinical examination, both vaginal and rectal, was helped by placing the patient in the Trendelenburg position and might be enhanced by putting the patient under chloroform. The use of the uterine sound, traction on the uterus with a volsellum, and filling the bladder or rectum with air or water assisted diagnosis in difficult cases. But after all means had been tried cases occurred in which the diagnosis was not clear, and as an extreme measure a diagnostic laparotomy was carried out. In exploratory laparotomy some operators preferred small incisions sufficient only to admit two fingers, but an examination in the dark did not aid much in the diagnosis and a longer incision was preferable, so that sight might assist touch in the examination. The results were poor and many such explorations through further interference became incomplete operations. Even with careful antiseptic and aseptic precautions exploratory incisions might be followed by peritonitis or sepsis. In malignant cases rapid increase of ascites after the operation might often delay healing of the abdominal wound, and such exploration greatly tended to a fatal issue. Professor Fehling considered that an exploratory puncture with a large-sized hollow needle or aspirator through the vaginal roof was of very great value in determining the nature of the tumour and its contents when it lay near the vagina. The vagina should be carefully prepared for the puncture and the patient should be kept at rest for at least 24 hours afterwards. The fluid obtained should be examined for blood, pus, and serum; also for gonococci or pyogenic germs, and if necessary a culture on agar or in bouillon should be obtained to determine whether the cocci still retained vitality or not. These points would assist in determining the time and method of operation. The chemical examination of the fluid was not of so much value, but it might help to some extent. Thus Pfannenstiel had shown that the pseudo-mucin of the cysto-adenoma of the ovary was distinguished by the fact that boiled with dilute acids it was converted into a reducing agent, a glyco-proteid which reduced copper oxide like sugar in Trommer's test. The results of exploratory puncture in 81 cases were given, and he concluded that the puncture of small tumours, especially those of the adnexa, was a harmless procedure and was useful both for diagnosis and treatment. Exploratory laparotomy should be avoided as far as possible.—Dr. HAULTAIN, Dr. BUIST, and Dr. FERGUSON discussed the paper.

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF ANATOMY AND PHYSIOLOGY.

*Presidential Address.—The Inferior Parietal Lobule.—Nerve Endings in the Auditory Tract.—The "Stomach Chamber"—Abdominal and Pelvic Viscera in a case of Advanced Pregnancy.*

A MEETING of this section was held on Jan. 31st, Professor D. J. CUNNINGHAM, the President of the section, being in the chair.

The PRESIDENT briefly reviewed the work done by the members of the section during the 19 years of its existence—work which reflected great credit on the section both for thoroughness and originality. It seemed to him to have been marked by three great waves, which he would take the liberty of naming the morphological wave, the cerebral wave, and the visceral wave. One of the first papers produced at the section, and he thought the first printed, was that very excellent contribution of Mr. Abraham on the Frequency with which the Musculus

Atrophy; the seventeenth chapter, on Tabes and Syringomyelia; the twentieth chapter, on Affections of the Terminal Cone—i e., the lowest part of the spinal cord; the twenty-second chapter, on Polyneuritis of the Lower Limbs or Anterior Poliomyelitis; the twenty-seventh chapter. on Juvenile General Paralysis; and the thirtieth chapter, on Infantile and Other Forms of Myxœdema. The other lectures are also excellent, and, indeed, there is scarcely a page of the book that is not replete with original remarks and pregnant with suggestions. In all cases the chapters begin with a summary, then follow a description of the case under consideration, the differential diagnosis, and finally the prognosis and treatment.

The reader naturally thinks of Charcot and the work which he carried out from 1882 at this hospital. He has found a worthy successor in Professor F. Raymond, who has most laboriously carried on since Charcot's retirement the course of study so advantageously begun. Of course, these lectures are not for all time, but they do give to the busy practitioner the opportunity of reference to what is probably the most complete history and symptomatology of prominent nervous cases to be met with in practice, according to our present enlightenment. What makes for the completeness of the accounts is that the assistance of other experts has been called in to ascertain with accuracy such particulars as the determination of impaired sensory skin areas, the results of applied electricity and galvanism, the performance of surgical operations where indicated, &c.; in fact, each case is a complete *résumé* of expert evidence, consolidated into a harmonious whole by the clear remarks of the professor. Under the names of Friedreich's disease, of Little's disease, of Thomsen's disease, and of symptoms such as those of Romberg, Argyll-Robertson, &c., the general reader is apt to be confused, but here he will not only find the names used but also explained. No work on neurology would be complete which did not include hysteria, and in its relations with different affections of the nervous system we find chapters on myoclonia and hystero-traumatism, the latter involving a discussion on the nature of "railway spine" as first described in this country by Erichsen and adversely criticised by Charcot, Thomsen, and Oppenheim. The theory sustained by Strumpell is that there exists a central traumatic neurosis which is clinically confounded with hysteria and neurasthenia, but is rather varied in its shades and degrees and is only grafted upon a soil predisposed to it With this theory Professor Raymond agrees. They are not afraid of loss of blood in France. In one case a patient (page 12) was operated upon for a cerebral tumour. On the first occasion he lost 50 ounces of blood; the next operation cost about 66 ounces of blood; on the third occasion the hæmorrhage was "formidable," but a tumour of the size of half an orange was removed by M. Chipault. On page 528 is found a useful *résumé* of the anatomy of the cortex of the brain with special reference to the system of tangential and radiating fibres, the alteration in which is important in the lesions met with in general paralysis. Each lecture is so bristling with interesting deductions that it is not needful to do more than to insist upon the instruction to be derived from the perusal of any part of the book

*Proceedings of the Society for Psychical Research.* Part XLI. Vol XVI. October, 1891 London: Kegan Paul, Trench, Trubner, and Co. Pp 649 Price 10*s.*

This volume is entirely devoted to a record of observations on certain trance-phenomena and comments founded upon them by Professor James Harvey Hyslop, Ph.D. It is divided into two parts. The latter half of the volume, roughly speaking (pp. 303 to 649), is made up of appendices containing a detailed report of the "sittings" which the writer had with a Mrs. Piper and on which he founded his papers. The record of the sittings is preceded by a brief preliminary note and is followed by Experiments on the Identification of Personality (Appendix IV.), Experiments in Communication through a Tube (Appendix V.), Experiments in Hypnosis (Appendix VI.), and quotations bearing on the mental condition of the communicator while communicating (Appendix VII.).

The subject of trance and the allied mental phenomena are of such interest to the medical profession and to the public that any genuine attempt to throw new light on them must be regarded with consideration. The whole subject of what is now called hypnotism has been of more or less general interest ever since the time of Mesmer, and there can be no doubt that "mesmerism" would have found a recognised place in surgical practice as an anæsthetic had not the use of chloroform been discovered just when it was. It unfortunately happened about this date that scientific problems of the greatest complexity were investigated by self-confident people of extraordinary credulity, and there were not wanting at that time a number of professional charlatans who reaped a rich pecuniary benefit from their *séances*. Of this period Carpenter in his "Mental Physiology" gave a good general account which can still be studied with profit. After the exposures of some flagrant cases of spiritualistic imposition, medical men, as a rule, thought it wiser to leave the whole subject severely alone. But the number and interest of the psychic problems which forced themselves upon people who would not shut their eyes to them made it impossible that they should be shelved entirely. The existence of a succession of peripatetic mesmerists who induced phenomena which could not be entirely explained as fraudulent served to keep these things before the public in the first place, and it therefore happened as a result of the general interest excited in the subject that medical men were often compelled to face scientific facts about which they had not been instructed in the course of their medical education. The Society for Psychical Research was inaugurated to investigate phenomena which had for so long, it considered, been unduly neglected and it has done a considerable amount of work. Some of the most energetic workers are now lost to it, and amongst them must be mentioned Professor Henry Sidgwick, Mr. Edmund Gurney, Mr. F. W. H. Myers, and Dr. A. T. Myers. The society, however, can still boast of having on its list of vice-presidents and council some few men of more than European reputation—for example, Mr. A. J. Balfour and Lord Rayleigh. The council has decided that "the responsibility for both the facts and the reasonings in papers published in the Proceedings rests entirely with their authors." Still, it must directly or indirectly rest with the council as to what it publishes. The names of the members of the council are printed on the cover of the Proceedings, and it must be held that they, or some persons acting for them, have decided that the book before us was worthy of being printed at the expense of the society. As to whether such an opinion is or is not well founded, we will not presume to say; it will be better to give a quotation of a report of one of the sittings in which Professor J. H. Hyslop took part, and to leave our readers to judge whether or not it was worth while to start "telepathic" or "spiritualistic" hypotheses to explain such like texts. On visiting Mrs. Piper the investigator, it should be said, had provided himself with a black mask "such as is used at masked balls," and "under this concealment" he was introduced to the lady, bowed without uttering a sound, and did not speak till she had gone into a trance, but he studied Mrs. Piper's reception of him. When she saw the mask she "broke into a laugh," and the laugh bore every external trace of sincerity. Mrs.

regained and in the other the vocal power, although not so good, was sufficient for all practical purposes

PATHOLOGICAL SOCIETY OF MANCHESTER —A meeting of this society was held on Feb 12th, Dr F Harris, the Vice President, being in the chair —Dr E F Trevelyan (Leeds) described the pathology of a very acute case of Meningitis secondary to Facial Cellulitis The staphylococcus aureus was obtained from a secondary abscess in the body and also from the exudation at the base of the brain The recorded cases of staphylococcus meningitis were briefly referred to —Dr A E Finney made a short communication on Myomalacia Cordis and its results —The Vice President and Dr F C Moore showed preparations from a case of Chloroma The patient was a boy, 14 years of age, whose illness commenced with symptoms believed to be those of sciatica The pain persisted in his left hip, and no further symptoms developed until a month before his death when he showed signs of orbital and intracranial growths He was admitted to the Manchester Royal Infirmary a fortnight before his death with partial paralysis of the lower and upper extremities, great pain in the left hip, marked exophthalmos of the right side, almost complete deafness, and bilateral facial paralysis He gradually became weaker and died about 13 weeks from the commencement of any indications of disease At the necropsy numerous nodular masses of new growth of a grass green colour were found in connexion with the inner aspect of the dura mater, with the periosteum of the orbits, of the vertebræ, the sacrum, and the iliac bones, and in the kidneys There was also a diffuse infiltration of the mesenteric lymphatic glands and of the connective tissue of the portal canals in the liver with a similarly coloured tissue The colour rapidly faded on exposure in the dark equally as in the light, becoming greyish green then greyish yellow The tumours histologically consisted of a fine fibrous reticulum with capillaries containing closely packed lymphocyte like cells The nature of the pigment had not so far been determined —Dr W Walter showed microscopical sections from a case of Primary Epithelioma of the Vagina in some of which the growth was seen to be of papillomatous origin and in others there was evidence of the epithelium having invaded the neighbouring tissues The patient from whom the specimens were taken was aged 37 years and was unmarried —Dr A W W Lea showed a series of Vaginal Growths, consisting of primary epithelioma, primary sarcoma papilloma, and fibroma

LEEDS AND WEST RIDING MEDICO CHIRURGICAL SOCIETY —A pathological meeting of this society, devoted to a discussion on the Pathology of Tuberculosis, was held on Feb 14th *Dr A G Barrs, the President*, being in the chair —Dr E F Trevelyan read a short paper on the Tubercle Bacillus In discussing its morphology he alluded particularly to the clubbed and branching forms Several acid fast micro organisms and some members of the streptothrix group were shown for comparison with the tubercle bacillus Dr Trevelyan said that he generally succeeded in getting a rapid growth (often in three or four days) on Heydenised media, especially when potato was added to them In examining sputum he used a pointed platinum spatula for making the film If after a careful examination of the sputum in cover glass preparations a negative result was obtained in a really suspicious case he preferred to employ the inoculation test at once, sedimentation methods had been of no real service to him A large number of bacteriological specimens prepared with the assistance of Dr Ursula Chaplin were shown in illustration of the various points alluded to —Dr S Long, Mr P J Cammidge, Dr Maule Smith, Dr T Churton and the President discussed the subject, and Dr Trevelyan replied —Dr F W Eurich (Bradford) dealing with the Anatomy of Tuberculosis, divided the tissue changes produced by the bacillus into the proliferative and inflammatory and showed how the manifold appearances of tuberculosis depended upon the relative proportions of these two factors —Dr E O Croft in describing a case of Tuberculosis of the Cervix Uteri said that the disease had developed in the cervical mucous membrane at the external os and had produced a localised growth of a papillary form (tuberculous papillary cervicitis) Sections through these papillæ and the adjoining mucous membrane showed typical tuberculous tissue The disease was apparently quite localised, the uterus and tubes being normal —Dr J B Hellier discussed the paper and Dr Croft replied —A large number of tuberculous specimens were shown, being arranged in various classes, including the nervous system, the respiratory system, the alimentary system, the genito urinary system and the bones and joints Animal tuberculosis was illustrated from specimens from the cow, pig, monkey, horse, and guinea pig A number of microscopic specimens illustrating tuberculous lesions were shown by Dr Maule Smith, Mr Cammidge, and Dr Eurich

BRITISH ORTHOPÆDIC SOCIETY —The seventh annual meeting of this society was held on Feb 15th, Mr John Poland being in the chair —The reports of the honorary secretaries and the treasurer showed that the society was in a sound condition —The following members were elected to the council Mr W Armstrong, Mr W E Bennett Mr J Carwardine, Mr J Jackson Clarke, Dr Percy Lewis, Mr T H Openshaw, Mr E Muirhead Little, Mr H A Reeves, and Mr Noble Smith Mr C R B Keetley was re elected treasurer and Dr A F Blagg and Mr Chisholm Williams were re elected honorary secretaries —An ordinary meeting of the society was then held —Mr Chisholm Williams showed a lad, aged 16 years and a girl, aged 19 years, with Rheumatoid Arthritis of the second, third, and fourth fingers of both hands He also showed a boy, aged 11 years, with entire Loss of the Power of Pronation and Supination due to congenital fusion of the bones of both forearms just below the bicipital tuberosity, one had been operated on and a false joint had formed just below the point of fusion, pronation and supination were slowly returning —Mr Jackson Clarke, Mr William Thomas, and Mr Poland commented upon the cases —Mr Jackson Clarke showed a case and a skiagram of Fracture Dislocation of the Head of the Radius in a woman aged 28 years He had operated and had removed the fractured part with excellent results —Mr Thomas read a paper on Excision of the Knee in Children —Mr Jackson Clarke read a paper on the Prevention and Treatment of Fracture Deformities —Owing to the lateness of the hour the discussion was adjourned to the next meeting

WEST KENT MEDICO CHIRURGICAL SOCIETY —The fourth meeting of the forty sixth session of this society was held on Feb 7th, Dr Thomas C Meggison, the President being in the chair —Dr R E Scholefield read a paper on Some Cases of Feigned or Functional Disease —The paper was discussed and cases were related by Dr F S Toogood, Mr L Clarke Dr L Ll B Williams Mr R V Donnellan, Dr J H Keay, Dr J P Henry, and Staff-Surgeon W W Pryn, R N

# Reviews and Notices of Books.

*Lessons on Diseases of the Nervous System, 1897-98* By Professor F RAYMOND Fourth series Paris Octave Doin With 59 Drawings and two Coloured Plates. Pp 606 Price 15 francs

THIS work consists of 18 chapters, most of them devoted to various special forms of disease involving the brain and the spinal cord These lectures, delivered at the Salpêtrière Hospital, form very complete clinical records of some of the most interesting and difficult subjects that engage the attention of neurologists, and for many reasons they deserve study Written in the most explicit French manner, expressed tersely and elegantly, they show a profound knowledge of the subject and an admirable capacity for analysis whilst in clearness and dignity of style they remind us more of the classical essays of Todd, Stokes, and Watson than of any other lectures in this country to which we can refer For thoroughness and up to date knowledge, for acuteness in differential diagnosis, and for detailed description of symptoms we have nothing but praise, and the work would probably repay translation For special prominence we select the first chapter, on Two Cases of Tumour in the Zone of Rolando, the third chapter, on Scleroses *en Plaques* in a Child, aged six years, the thirteenth chapter, on the Different Varieties of Progressive Muscular every convict contemplating photographs of his relations in his cell, both of which extremes of penology are combined in the system suggested by Mr. Whiteway. At the same time, his essays are not uninteresting, and, if they tend to stimulate thought and action upon what is really an important subject, will not be without usefulness. Their effect, however, would have been assisted if their author could have cultivated a terser and more concentrated style; moreover, he might have revised his proofs more carefully.

*Medical Diagnosis, with Special Reference to Practical Medicine.* By J. M. DA COSTA, M.D., LL.D., Physician to the Pennsylvania Hospital. Ninth edition, revised. London: Smith, Elder, and Co. 1901. Pp. 966. Price 24*s.*

A WORK which has reached the ninth edition requires but few words from the reviewer as to its object and scope. Suffice it then to say that the aim of the author has been to furnish advanced students and young graduates of medicine with a guide that might be of service to them in their endeavours to discriminate disease. He has sought to offer to those members of the profession who are about to enter on its practical duties a book on diagnosis of an essentially practical character, one neither so meagre in detail as to be next to useless when they encounter the manifold and varying features of disease, nor so overladen with unnecessary detail as to be unwieldy and lacking in precise and readily applicable knowledge. In these endeavours Dr. Da Costa has admirably succeeded. In plain and precise language he describes the various symptoms and signs which may be met with in the examination of patients and the conclusions which may be drawn from them. Physical signs can only really be learned and studied at the bedside or in the out-patient room; and not only must these signs be recognised but they must be carefully interpreted. It is in this latter direction more especially that a text-book of the nature of the one now under consideration is of value. The student should first examine patients under the direction of the physician and he may then turn to his books for a full consideration of the meaning of the physical signs which he has detected or which have been pointed out to him.

The present edition has been brought fully up to date, although there are still to be found certain statements which should have been omitted as having been disproved or rendered so doubtful as to make their repetition misleading, such, for instance, as that appendicitis may be caused by "cherry-stones." A large amount of new matter has necessarily been incorporated in this edition, especially in the chapters on the Diseases of the Stomach, on the Blood, and on Fevers. The most important advances in bacteriology have also been inserted under the headings of the various diseases concerned. The numerous illustrations considerably add to the value of the book and a very full and elaborate index greatly facilitates reference.

*The Criminal Mind.* Translated from the French of Dr. MAURICE DE FLEURY. London: Downey and Co. 1900. Demy 8vo. Pp. 196. Price 3*s.* 6*d.*

THIS is a translation from a popular account of the criminal as a subject for psychological and social study, written by Dr. Maurice de Fleury who states in the introduction that his object is to present a *résumé* of the most recent and clearly established ideas on the subject, the acceptance of which is calculated to modify current and popular ideas upon crime, the criminal, and penal legislation. The author starts from the scientific doctrine of determinism as opposed to the metaphysical (and legal) view of free will, and incidentally points out how the craving of the public for sensationalism has led newspapers generally to magnify or to distort criminal deeds in several notorious instances. The attitude of the public is thus changed into one of vengeful resentment rather than of judicial fair-mindedness to the accused and is liable to ignore the claims of justice. The crowd is readily provoked to brutality and to blind passion.

After a brief anatomical sketch of the brain, with illustrative diagrams of its cortical "centres," memory and consciousness are touched upon, and the "personality" is shown to be an aggregate of sensory centres inter-connected with, and reciprocally influencing, one another. The organic basis of emotions is emphasised, and looking upon education and bringing up as counter-agents to strong hereditary propensities, the author claims that the human organism may be capable of varying degrees of ethical and intellectual development. The true or natural criminal, it is argued, experiences little remorse because he is mentally defective. The habitual criminal, also, as Dr. de Fleury points out, often shows evidences of neurasthenia and incapacity for steady work and frequently is the bearer of a neurotic taint, and is more suitable for the hospital or asylum than for the prison. Regarding prophylaxis, Dr. de Fleury urges the need for dealing with such factors as overcrowding, slum life, and intemperance which are agencies in the production of criminality. Education may do much to reform both the *gamin* of the boulevard and the Hooligan of the slum. Philanthropic societies exist in many countries to carry out these ideas of reform and rescue. In these directions the outlook is hopeful.

The book is clearly and popularly written and, though a little diffuse in style, may be recommended as a helpful introduction to the subject, especially for lay readers.

*"Prosperous" British India: a Revelation from Official Records.* By WILLIAM DIGBY, C.I.E. London: T. Fisher Unwin. 1901. Pp. 661. Price 12*s.* 6*d.*

THIS very elaborate work, the preparation of which must have entailed an enormous amount of labour on the part of its author, is one which scarcely falls within the province of a medical journalist to review. It is due, however, to the author's labours and earnestness of purpose that we should state our impressions. *If* the pessimistic picture which the author paints of India and of the results of our government of that country be true, if our rule has been attended with all the evils depicted and has only been productive of such an increasing impoverishment and misery of the people as is represented, it is certainly time to set about some inquiry into the facts with a view to remove the delusion under which the statesmen and people of this country are labouring and to take some measures which may lead to the amelioration of the condition of many millions of British subjects. That India has an enormous population (miserably poor for the most part), and that it has of late years been terribly tried by plague, pestilence, and famine, there is no doubt; but are all the alleged facts set forth in the volume before us to be taken as established and, if so, have they been brought about by, and been attributable to, our misrule? That, as it seems to us, is the issue, and it amounts to a very big indictment

The author, as he confesses, writes "impassionately from a full heart," but also, he adds, from an "equally full mind." At page 64, after quoting an eloquent speech of Macaulay made some 70 years ago, on what should be the aim of our administration of India, the author alleges that the scheme of the upliftment of India as set forth by Macaulay no longer arouses interest among so humane a profession as THE LANCET represents. It is not, we should say, so much from any lack of interest in the well-being of the natives of India on the part of anybody as from want of any practical knowledge of how to give effect to it. In other portions of the

Piper, "after dusting some articles in the room ..... sat down upon her chair for the trance." Pillows had been placed in front of her for her head to lie upon "while entranced." The investigator closely watched the trance coming on. After an interval of quiescence he noticed a few slight jerks of the head and some twitching of the right eyebrow, "Mrs. P. picking the while at her finger nails." Afterwards she leant forward on the pillows, closed her eyes, rubbed them, &c., and later "returned to picking her finger-nails." At a later period the expression of her face changed and finally "she passed easily without a struggle into the trance." Then she wrote as follows: "Good morrow, friend of earth. We see old friend and we welcome thee here. We see all that thou hast done since we met thee last and we are pleased with all that is coming to thee." There are pages of trance literature, of which the above is the opening. That brief citation may suffice. The investigator's interpretation of the trance-phenomena the curious reader may be confidently left to discover for himself should he think fit. It would not be kind to spoil his pleasure by discussing it, and it need only be said in this connexion that the work is most seriously undertaken. There was one matter on which information would have been welcome. It is recorded more than once that Mrs. Piper picked her finger-nails, and we were led to hope that we might have learned something more of the present situation—or, in deference to Professor Hyslop, we will say the present "location"—of that "peck of pickled pepper" the mystery of which is connected with the memory of Mr. Peter Piper.

---

*Tumours, Innocent and Malignant: their Clinical Features and Appropriate Treatment.* By J. BLAND-SUTTON, F.R.C.S. Eng., Surgeon to the Chelsea Hospital for Women; Assistant Surgeon to the Middlesex Hospital, London. New Edition, with over 300 Engravings. London: Cassell and Co. 1901. Pp. 570. Price 21*s*.

THE very remarkable reception which was accorded to this work on its first appearance must be in chief part attributed to the novel method in which the subject was treated. The frequent appeals to comparative pathology threw a light upon many obscure problems and the whole arrangement of the subject showed that the volume proceeded from the pen of an original thinker and one well acquainted with pathology. Many of the ideas were new and no small number of them at once met with a wide acceptance, though others have had considerable doubt cast upon them. We reviewed so fully the first edition of this work that but little remains to be said of this second edition. We may perhaps point out that the histological structure of growths is not very fully dealt with although it is frequently referred to. Into the difficult question of the causes of malignant tumours the author does not venture to enter; he tells us "they are unknown." This is doubtlessly true, but of recent years so much has been done in the investigation of this subject that we should have liked to have had Mr. Bland-Sutton's opinion of the present position of our knowledge. The references to the sources from which the author has drawn his materials are very numerous, and these are especially useful to those who wish to examine further into any of the many matters treated here. Very useful, also, are the two indexes, one containing the organs and the other the tumours

We should like to ask Mr. Bland-Sutton what authority he has for saying that compact osteomata, such as those in the frontal sinus or on the vertex of the skull, are capped with cartilage. He says that compact osteomata may occur on "almost any part of the skeleton." We believe that in this account the author is confusing two entirely distinct tumours. It is true that on the bones of the limbs and even on the skull growths may occur which consist of compact bone and are capped with cartilage by which they grow. These, no doubt, deserve the name of "compact osteomata," but there are other tumours chiefly affecting the frontal, parietal, and temporal bones, composed entirely of a much harder and denser form of bone. These are always sessile and never at any period of their growth contain any cartilage. These true "ivory" osteomata should certainly be distinguished from the ossified chondromata which consist of compact bone.

---

*Recent Object-lessons in Penal Science.* With a Bibliographical Introduction. By A. R. WHITEWAY, M.A., Barrister-at-law, Corresponding Member of the Academy of Legislation of Toulouse. Third Series. London: Swan Sonnenschein and Co., Limited. 1902. Pp. 216. Price 3*s*. 6*d*. net.

MR. WHITEWAY in a brief preface ingenuously informs us that chapters written originally for magazines and reviews do not lend themselves over-kindly to revision for publication in book form—a fact which in any case would have been discovered by those who perused his work with any care, for there is repetition and even inconsistency, real or apparent, in the small volume before us which careful revision or re-writing would have prevented. A book the chapters of which are disconnected essays on kindred or identical topics is apt to be confusing and does not easily lead to a definite conclusion or excite the interest that its subject merits. The conclusion at which Mr Whiteway appears to have arrived is that England is behind America, France, Italy, and some other nations in the interest which it takes in the welfare of its criminals, but he does not, perhaps from lack of space, go so far as to satisfy us either that the criminal is, as a rule, better treated by the country that is most prolific in "penologists," or that in the country where the "penologist's" experiments have the widest and most varied scope crime is diminished and criminals are reformed into citizens to an extent without parallel elsewhere. In addition, Mr. Whiteway does not consider that the Prisons Act of 1898 has taken us far enough. He wishes to see wider distinctions made between criminals, so that our prisons may be to a large extent compulsory hospitals for moral cripples confined in them by indeterminate sentences—sentences, that is, varying in length in accordance with the time occupied by the moral cure. That more can be done in the direction indicated than is done under our present conditions is undeniable, nor is it to be gainsaid that in many cases it might be done successfully. The difficulty, however, of diagnosing moral disease and establishing moral cures upon the scale apparently contemplated by Mr. Whiteway is, perhaps, greater than he would be prepared to admit. Meanwhile the recent Prisons Act already referred to, if carried out in a liberal spirit and with a sufficient expenditure, may with the help of prisoners' aid associations take us some way in the right direction, while improved conditions of social life for the poorer classes are more likely to diminish crime by prevention than moral hospitals can ever hope to do by cure.

Those who are not aware of the extent to which penologists differ from one another will do well to turn from Mr. Whiteway's remarks upon the American penal institution known as Elmira to the work on "Penological and Preventive Principles" published by Mr. Tallack, secretary of the Howard Association. There they will find Elmira with its Turkish baths and massage dealt with under a chapter headed "The Social Crime of Cruel Laxity." A further study of literature of this class will cause them to hesitate to endorse Mr. Whiteway's aspiration that all judges and magistrates should be penologists. Such judges and magistrates might hold views varying between the desire to punish garotters by six months' imprisonment with 12 strokes of the "cat" every other month, and the wish to see recognising the advantages of closer inter-communication with the colonies, for which purpose authoritative lists of the medical men in the various principalities and dependencies of our empire are necessary.

*Where to Buy: A Guide to the Professions and Business Houses.* By C. M. KNOWLES. London: Simpkin, Marshall, Hamilton, Kent and Co., Limited. 1902. Pp. 192 Price 3*s.* 6*d.*—This silly little book purports on the title-page to be "a guide to the professions and business houses, showing what are their specialities and where all goods may be bought to the best advantage, with interesting notes." We have not found that it fulfils the author's promises. The omissions frequently are flagrant, the contents not seldom are incorrect, and the notes are dull or ridiculous. Under the heading "Professional and Educational" six unfortunate members of the medical profession are pilloried as eminent people in such company as Sandow "the patentee of a dumb-bell," and John D'Auban who "teaches ladies' skirt and fancy dancing." They are Sir William Broadbent, who is described as "Censor to the Royal College of Physicians"; Sir Francis Laking, who is stated to be "House Physician to St. George's Hospital"; Dr. W. A. Wills, of whom it is said that he was once "House Surgeon to Brompton Hospital"; Dr. J. Little, who "pays income-tax on £10,000 a year"; the late Sir William MacCormac; and Mrs. Scharlieb. A cursory glance through the book leads us to the belief that the rest of the information is of about equal value. Of hospitals, only three of the large general hospitals of London are mentioned in this professional guide, and, oddly enough, they are arranged in a sub-class under the heading "Where to Live," which includes the Athenæum Club, the Savoy Restaurant, the Piccadilly branch of the Aerated Bread Company, Limited, and Broughton Hall, Staffordshire. Under the head of "Literary" we learn that Mr. Waldroff (*sic*) Astor is rich, that Sir William Ingram owns a very fast dog, and that Mrs. Humphry Ward, author of "Manners for Men," writes "Girls' Gossip" under the *nom de plume* of "Madge." These, we presume, are examples of the "interesting notes." What conceivable purpose can such a book serve?

*Clinical Lectures on the Various Forms of Intra-abdominal Suppuration.* By A. H. TUBBY, M.S. Lond., F.R.C.S. Eng., Surgeon to Westminster Hospital and Senior Surgeon to the Evelina Hospital for Children. London: The Medical Publishing Company, Limited. 1901. Pp. 100. Price 3*s.* 6*d.*—These lectures were delivered to the students of the Westminster Hospital Medical School and have already appeared in the *Clinical Journal.* When we remember that at least two-thirds of the cases of abdominal suppuration are connected with inflammation of the vermiform appendix we need not be surprised that four out of the seven lectures contained in this book are concerned with appendicitis. The subject is treated very fully and carefully, but the account is very readable. The most difficult point to decide when a diagnosis of appendicitis has been made is when to operate. Mr. Tubby comes to the following conclusions: (1) if operation is necessary the sooner it is done the better and the greater are the chances of recovery; and (2) the basis of the decision should be the character of the attack and not the duration of the illness. Sub-diaphragmatic abscess is often a very perplexing condition and the chapter devoted to it should prove useful to those who are unacquainted with this variety of abdominal suppuration.

*The Sanitation of British Troops in India* By E. CARRICK FREEMAN, Major, R.A.M.C. Second edition, revised and enlarged. London: Rebman, Limited. 1901. Pp. 127. Price 2*s.* 6*d.*—A second edition of this little book having been called for the text has been revised and two appendices added—one relating to malaria and the other embodying some lessons gained from South African experience. It may be succinctly described as giving much useful elementary information about the systems and methods of procedure followed in India and how to turn them to the best account. As regards the seasonal prevalence of enteric fever we were under the impression that according to statistical evidence the periods of increasing prevalence of this fever were shortly before and after the rainy season. The author tells us that Mr. Ghadialli, Professor Hankin's assistant, claims to have discovered a micrococcus which has an inhibitive influence on the enteric fever bacillus. Further experiment is, however, required in the matter, although it is stated to have given good results at Lucknow when introduced into an infected well. It would be of interest to learn further particulars in regard to this micrococcus. The new chapters on Malaria—briefly outlining the modern theory and views—and on Active Service (South Africa)—setting forth some points bearing on the sanitation of troops in the field—are additions which have been called for by the progress of events. The work contains much information shortly put which is likely to prove serviceable to medical officers newly arrived in India.

*Use-inheritance, Illustrated by the Direction of Hair on the Bodies of Animals.* By WALTER KIDD, M.D. Lond., F.Z.S. London: Adam and Charles Black. 1901. Pp. 47. Price 2*s.* 6*d.*—This is an attempt to prove the inheritance of acquired characters from observations on the direction of the hairs on the bodies of animals and man. It does not deal at all with the general inclination of the hair, for "whether the hair should slope from the cephalic to the caudal end of the trunk of an animal or the reverse ...... is of extreme importance to the well-being and perhaps safety of the animal," and will therefore be determined by natural selection. It deals with the local variations of the general inclination of the hair, and the author considers that these local "whorls" of hair are produced chiefly by the action of muscles. He shows that many of them are peculiar to individual species and that they vary greatly in different individuals and therefore he claims that selection is incompetent to produce them. The work is of interest and is based on very careful observation of a large number of facts. Dr. Kidd's point cannot, however, be considered proved. Experimental evidence would be of very much greater value. Can the author modify the direction of the "hair-flow" in an animal so that it may be transmitted to its descendants? Along this line probably lies the proof of the transmission of acquired characters, if, indeed, they ever are transmitted. Still, the little work should be read by those interested in the problems of inheritance.

## JOURNALS AND MAGAZINES.

*The Journal of Hygiene.* Vol. II., No. 1. January, 1902. Cambridge: University Press. Price 5*s.* net.—Dr. T. E. Hayward, the medical officer of health of Haydock, Lancashire, contributes to this number of the journal a very helpful and suggestive paper on the Construction and Use of Life-tables from a Public Health Point of View. The publication of this article at the present time is very opportune seeing that the recent census figures will soon be available and that medical officers of health will hence be glad of assistance in life-table construction. Dr. Hayward first describes the construction of a complete, or what is technically known as an "extended," life-table, and he then points out the uses which may be made of such a table. Finally, he shows that by a modification of the late Dr. Farr's "short" method it is possible to reach results "which are practically identical with those worked out by the much more laborious extended method." We commend Dr. Hayward's article to all those who are contemplating the construction of life-tables for their volume Mr Digby refers to some famine statistics furnished by our Indian correspondent and published in this journal

After looking over some 640 pages of what may be termed destructive criticism we turned to that section of the book devoted to "The Remedy,' but we confess to a feeling of disappointment at finding that it consists of three pages to the effect that the statement of the evil is, for the moment, enough and that any consideration of the remedies is postponed until some agreement is arrived at as to whether any need for remedy exists Recognising the time and labour which must have been expended in the compilation of this work we cannot doubt the author's earnestness, but we should like to know how he proposes to deal with the alleged evils After all that has been said and written about Indian finance and the causes of distress in India there are matters connected with the climate and soil, over-population, and the habits, customs, and traditions of the people that are quite beyond our control, but which have, nevertheless, always to be borne in mind and taken into account

## LIBRARY TABLE

*Outlines of Anatomy* By EDMUND W HOLMES, M D, Demonstrator of Anatomy, University of Pennsylvania, 1892–1901 Lancaster, Pa The New Era Printing Co 1902 Pp 185 —This unassuming little book is simply a collection of notes for the student as to what to do in the dissecting room It should be found of great value, and we quite *agree with Dr Holmes in his remark in the intro*duction that "wet specimens and models should be largely used in the early days of the session for the novice" Anatomy as usually *taught* is *singularly* uninteresting, and we do not think that the reason for anatomical facts is sufficiently pointed out to the beginner The average student, for instance, who is beginning the study of anatomy does not know, or possibly does not think, why a limb should have bones, why the bones should have muscles, why the muscles should be supplied with nerves and arteries and veins, and so on If this is explained to him first on a wet specimen before he begins to dissect he will, at all events, have an idea of what he is going to look for

*The Röntgen Rays in Medical Work* By DAVID WALSH, M D Edin Third edition London Baillière, Tindall, and Cox 1902 Pp 316 Price 12*s* 6*d* —This is the third edition of Dr Walsh's valuable book, it exhibits one new feature in that the introductory portion—namely, that upon apparatus and methods—has been re written by Dr Lewis Jones The medical and surgical applications of the rays are described with great care and by means of an appendix the subject has been brought up to date There are plenty of illustrations which are admirably reproduced Altogether the book is an excellent treatise upon what is so far known of a comparatively modern development of natural forces

*Thoreau His Life and Aims* By H A PAGE A new edition London Chatto and Windus 1901 Pp 271 Price 2*s* 6*d* —We cannot say that a perusal of this book gives us the information which we should expect from its title Mr Page is *evidently* a *lover* of Thoreau, but his book consists of little more than excerpts from "Walden,' to which work we should prefer to refer anyone *who is anxious* to know what manner of man was Thoreau Shortly we may say that he was a natural philosopher with a good deal of mysticism in his nature He was bored by his fellow creatures and being able to get away from them he squatted in the Massachusetts woods and built him a house where, to use a phrase of Kipling he sat down and let the wild things run over him His experiences are recorded in "Walden, a book *which is not* read so much as it should be

*Rough Notes on Remedies* By WILLIAM MURRAY, M D Durh, F R C P Lond London H K Lewis 1901 Pp 176 Price 4*s* —We need do no more than recall to our readers the main points in Dr Murray's excellent little book The chapters upon Belladonna, Calomel, Old Liqueur Brandy, and Mercury in Heart Disease may be read over and over again with delight and profit Thus the fourth, edition contains an addition in the shape of a chapter upon Rothbury as a Health Resort Rothbury is a little-known village in the valley of Coquet It lies in a most interesting district and the jaded town dweller could scarcely do better than go there It is, of course, not suited for every case of disease, the air being too strong But for a holiday it is an ideal place, and apart from its own interests the neighbouring places, such as Belsay, Elsdon, and Scots Gap, are full of "objects of interest,' as guide-books say Dr Murray has done well to call attention to Rothbury, but we hope that his advocacy will not be the means of introducing there that offensive person, the speculative builder

*Official Year book of Scientific and Learned Societies of Great Britain and Ireland* London Charles Griffin and Co, Limited 1901 Pp 347 Price 7*s* 6*d* —This useful compilation gives lists of papers read from January, 1900 to June, 1901, before societies engaged in fourteen departments of research besides information as to the meetings, membership officers, and publications of the various societies mentioned It is a veritable "Whitaker" of scientific societies

*The Principles of Hygiene* By D H BERGEY, A M, M D, First Assistant, Laboratory of Hygiene, University of Pennsylvania 1901 Philadelphia and London W B Saunders and Co Pp 495 Illustrated, Price 13*s* —This book deals with the principles underlying modern practices in the department of public health and will be found suitable for the needs of medical officers of health and those interested in public health, engineering, and architecture. It deals with the chemistry of hygiene in general—with personal, military, naval, industrial, and school hygiene There are good chapters devoted to Quarantine according to the Laws of the United States of America, to the Vital Causes of Disease, to Disinfection, and to Statistics bearing on the Census the Birth rate and the Death-rate The book is not suitable for the needs of those students in our British Universities who are preparing for diplomas in public health and is not in the least likely to take the place of, or to be preferred to, the excellent text books at present in use At the same time, it is written in an able and interesting manner and is one which may be kept on the library bookshelf for reference Several of the subjects are treated in a somewhat novel manner and the whole work bears evidence of careful preparation and a good deal of deep thought and research In the United States a Bill is passing through Congress *which when enacted will make the employment of the metric* system of weights and measures compulsory in all Government departments The metric system has, therefore, been used throughout in this work except in quotations What few illustrations there are in the book are well executed, though far from being original drawings On the whole, the work deserves favourable notice and the new ideas are welcome

*Natal Medical Dental and Pharmacy Registers, 1900* Pietermaritzburg P E Davis and Sons Pp 80 —We have received the official registers of the Natal medical and dental professions, to which is also appended a list of the chemists and druggists admitted to practise in the Colony of Natal up to the date of July, 1901 It may be noticed also that the registers of medical practitioners and dentists are verified up to July 1st, 1901 although the publication is dated 1900 It is becoming of increasing importance to the medical profession at home that colonial registers should be carefully and accurately kept; the medical profession like all other sections of the British Empire is

THE LANCET.

*LONDON: SATURDAY, FEBRUARY 22, 1902.*

# The Midwives Bill.

THE Bill "to secure the better training of midwives and to regulate their practice" is down for second reading on Wednesday Feb 26th and it has obtained a place which makes it likely that it will be read for the second time. We publish the text of the Bill on page 542 of this issue and would remind our readers that it is imperative that they should make up their minds what course they desire Parliament to pursue, for they must bring without delay what influence they may possess to bear in the desired direction. For our own part, we have no doubt that the Bill to be read next week is a mischievous one, and we are certain that a vast majority of our readers will share this view, or perhaps we should not be so ready to counsel them to give effect to their feelings. In commenting upon the Midwives Bill, introduced by Mr TATTON EGERTON just two years ago, we pointed out, as one of the main difficulties of what is known as "the midwives question," the fact that both those who do and those who do not desire legislation for the regulation of the practice of midwives can, with equal force, maintain that their opinion is the right opinion on humanitarian grounds and no less on medical grounds. To leave the parturient poor to the mercies of the GAMPS is cruel, but to supply them with a semi-educated grade of medical attendants is no kindness. If the first course leads to disasters the second would seem as inevitably to make for tragedies True, in the various shapes in which a measure for the regulation of the business of midwives has been before Parliament and the public, conscientious attempts have been made to escape from the dilemma; but the attempts have not been successful, and the Bill which we publish to-day is worse than some of its predecessors. It is in several directions more likely to institute an inferior order of general practitioners and thereby to work in opposition to the public weal.

To begin with, the latest edition of the Midwives Bill contains no penalty whatever to be imposed upon any woman, whatever her absence of qualifications, for "habitually and for gain attending women in childbirth": any woman can attend confinements and charge fees for her services. Should this Bill ever become law it will be open, as far as we can see, to any woman to continue to pursue the vocation of a midwife, with the single disability that she will not be able to sue for fees. Has the fact that quacks are unable to obtain in the law-court payment for medical service rendered in any way contributed to keep down the number of quacks? Of course it has not, and so long as there is no pecuniary fine to stop the first female who chooses from calling herself a midwife and spreading puerperal fever in return for money we are certain that prospective difficulties about her fees before a county-court judge will never give her pause in her dangerous career. The last Midwives Bill contained a clause fining women who after the passing of the Bill practised midwifery save in conformity with the regulations of the Bill, and the alteration of this clause is a distinctly retrograde step. Again, the present Bill appears to take the control of the purely medical side of the question out of the hands of the General Medical Council by saddling the Lord President of the (Privy) Council with the responsibility of seeing to the formation of the Midwives Board. Two years ago the fourth clause of the Midwives Bill read: "On the passing of this Act the President of the General Medical Council shall take steps to secure the formation of a Central Midwives Board," upon which general statement followed the scheme for the constitution, duties, and powers of the Board. The fourth clause now substitutes "the Lord President of the Council" for "the President of the General Medical Council." Moreover, the framing of the rules with regard to the practice of midwives is now made subject to the approval of the Privy Council, while in the previous Bill the General Medical Council was responsible for the regulation of the course of training and the conduct of examination of candidates for the midwives' roll. It may be said that the Bill provides for the consultation of the General Medical Council by the Privy Council, but medical men, at any rate, will not be much impressed by this concession. Doubtless neither the Duke of DEVONSHIRE nor Sir JOHN GORST are permanent officials; but what guarantee have we that future Presidents and Vice-Presidents of the Privy Council will discharge their duties towards the medical profession in a more efficient manner? The two distinguished members of the Government whose names we have just mentioned, when a question of vital medical importance was under discussion, admitted that they did not know anything about the matter because they had not read the reports of the General Medical Council. What security has the medical profession that advice tendered to the Privy Council by the General Medical Council on the scope of the midwife's duties will not be treated with a like disregard?

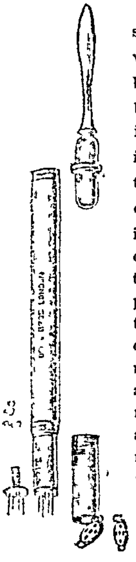
It may be remembered that just previously to the second reading of the Midwives Bill of 1900 we received at this office, in response to our invitation, 7250 communications from English medical men giving their attitude as to the proposed legislation. An analysis of these replies showed 1547 medical men to be in favour of the Bill, 640 to be indifferent, and the remaining 5000 odd to be opposed to it. Nothing has happened to make medical men change their opinions, and, as we have shown, such differences as exist between the Bill of 1902 and the Bill of 1900 are not for the better. We think that the time has come for interference on the part of the General Medical Council. The present Bill does not at all conform to previous directions of the Privy Council that certain points should be conceded by the promoters in deference to the views of the General Medical Council. The chief of these views may be summarised in the following words:—

The unlicensed practice of midwifery for gain as well a the false use of titles should be made illegal.

The functions of the Midwives Board should include the framing of the regulations for the conduct and practice of districts. Dr. Arthur Stanley, medical officer of health of Shanghai, furnishes some interesting notes on an Outbreak of Cattle-plague and of its control by the method devised by Professor Koch of injecting small quantities of the gall from an animal already dead from the disease into the cattle of an invaded herd. The results in the outbreak in question were eminently satisfactory, and the method possesses the advantage that the reaction produced by the injection of the gall has no disturbing influence upon the secretion of milk, a fact which will commend the practice to dairy-farmers and others. The Geographical Distribution of Anopheles and of Malarial Fevers in Upper Palestine is the subject of a communication by Dr. John Cropper. He found that malaria prevailed wherever anopheles represented the majority of the mosquitoes present in native dwellings, that the disease occurred mainly among children, and that it was absent or occurred in a sporadic form only in places where anopheles was not found. The *study of the Structures and Biology of Anopheles is carried* on in the current number of the journal by Dr. George Nuttall and Mr. Arthur Shipley, and many very interesting and instructive facts are brought forward. This is especially the case with regard to the musical appreciation of anopheles. Not only is it attracted by certain musical sounds, but the note produced by certain electrical vibrations has apparently a peculiar fascination for the males who seem to recognise therein the female insects. The volume under notice concludes with a paper by Dr. E. W. Ainley Walker on the Protective Substances of Immune Sera in which he discusses in the light of his own experimental work some of the recent developments of Ehrlich's theories.

# New Inventions.

## AN IMPROVED FORM OF VACCINATOR.



MESSRS. DOWN BROTHERS have at my suggestion made an improved form of vaccinator. Hitherto the Cooper-Rose has been one of the most popular in use, but the chief objection to it—the point, i.e., which the Local Government Board inspectors *invariably* find fault with—is the inablity thoroughly to asepticise the cap, where some material for microbic infection is bound to remain. Moreover, not being able thoroughly to cleanse the cap rust is apt to form, thereby preventing the needles from protruding through properly. To obviate these difficulties Messrs. Down Brothers have manufactured a cap which can be opened at once and the interior made thoroughly aseptic and dried, closing up again tightly, and thus fulfilling the requirements of a thoroughly aseptic vaccinator

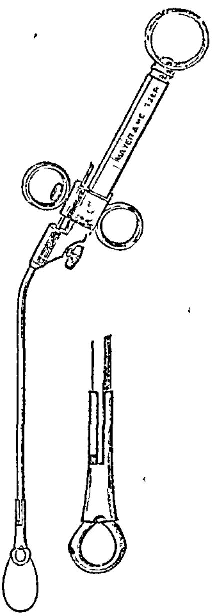
## A SELF-LOOPING NASAL POLYPUS SNARE.

MESSRS. MAYER and MELTZER have recently made for me a snare that I have found very useful. It consists of a Krause's snare with a Y-shaped end-piece fitted; the two upper ends of the Y are joined by a curved surface and the polypus is caught between the wire and this surface. The loop is tightened in the usual way by approximating the finger-plates. By simply separating the finger-plates not only does the polypus drop off but the loop is re-made without any of the usual fingering. With this instrument polypus after polypus can be snared without once taking one's fingers from the finger-plates, without any assistant preparing loops, and with a great saving of time, which, from the patient's point of view especially, is a great gain. As there is no twist or knot in the wire it has not the usual tendency to break. In addition to its use for simple polypus it is particularly adapted for the removal of moriforms from the posterior end of the inferior turbinal, as the instrument can be passed without difficulty with the loop retracted and when in its right position the loop can be ejected, when it will take on any curve to which it has been previously bent. The instrument can be had with end-pieces of varying size and could be used for the larynx as well as for the nose. Messrs. Mayer and Meltzer can supply the instrument complete or will make the addition to a Krause snare for a small sum. Mr. Hunter F. Tod told me when I showed the instrument at the Laryngological Society of London that he had seen a somewhat similar instrument in Vienna, but judging from an illustration there are many differences.



Nottingham place, W. ATWOOD THORNE.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Feb 13th, Mr. H. G HOWSE, the President, being in the chair.

It was agreed, as recommended by the Court of Examiners, that one set of surgical instruments should be lent to the University of London for the purposes of the M.B. and B S. examinations.

The PRESIDENT reported that he had chosen Mr. Howard Marsh as Bradshaw Lecturer for the ensuing collegiate year.

A letter was read from the Clerk of the Privy Council stating that it had been determined to hold the Medical Congress at Cairo from Dec. 19th to 23rd next, instead of from the 10th to the 14th. Mr. Reginald Harrison was appointed as the delegate from the College to this Congress

THE COTTON DISTRICTS CONVALESCENT FUND —The above title seems to suggest an echo of the distant past, for those who remember the cotton-famine resulting from the American war of North and South belong to a former generation. A meeting of the governors of the Fund was held in Manchester on Jan. 30th, when the Hospitals and General Purposes Committee was appointed as were committees to represent the governors on the boards of management of the convalescent hospitals at Southport and Buxton. During the past year 2815 patients were sent to the convalescent hospitals at a cost of £4797.

will by no means give a corresponding increase to the amounts paid to the companies, for they are legally compelled to supply water for municipal purposes at a fixed and moderate price. Enough has been said, it may be hoped, to convince any unprejudiced person that it would be a monstrous injustice to the London people to handicap a new board, nominally appointed in their interest, by saddling it with the responsibilities of undertakings about the ins-and-outs of which it is ignorant.

It would be easy to criticise the details of the Government Bill. We have been content to show that it is vicious in principle, while we think that it may be useful to indicate in brief outline the way in which a board, fairly representing the whole of "Water London," might be properly constituted and with what duties it should be entrusted. The board should be essentially a Board of Control. It should exercise supervision over the working of the present water companies and should investigate the problem of the future requirements of the whole district for which it would be responsible. The board should ensure that the existing statutory provisions for the control of the companies are rigidly carried out. The provisions are stringent, but little attempt has hitherto been made to enforce them. The late vestries were as a rule very indifferent in the matter and the London County Council has done practically nothing. The Local Government Board has been content to issue periodical reports which few people read. A Water Control Board is much wanted in regard to the constitution of which the chief desiderata are (1) that the customers of each company should be represented, and (2) that the board should not have too many members. The privileges and duties assigned to this Board should include not only he powers of control at present in force, but its sphere of influence should be made to cover financial matters, as well as the recommendations of the Balfour and Llandaff Commissions, which have hitherto been entirely neglected.

## The Aerial Convection of Small-pox from the Hospital Ships in the Thames.

WHAT is known by the somewhat grandiloquent phrase "the march of truth" is liable under certain adverse circumstances to degenerate into a halting and wearisome perambulation. This is most likely to be the case when the acceptance of the truth involves the direct negation of preonceived ideas, and when the demonstration of the thesis t forward depends upon certain natural phenomena which occur but rarely in necessary association. When well-nigh a quarter of a century ago Mr. W. H. POWER, F.R.S., now Principal Medical Officer of the Local Government Board, made his memorable inquiry into the behaviour of small-pox around the Fulham Small-pox Hospital, and when, as the result of such investigation, he enunciated the proposition that the phenomena which he had observed could only be adequately explained on the view that the infection from the hospital had been air-borne, and not carried by human intercourse, a storm of something akin to derision greeted the announcement. The theory was not only new: it was inconvenient.

A Royal Commission considered the matter, but its members were so staggered by the proposal that they sought refuge upon the fence until more light should be forthcoming. No less an authority than Sir JOHN SIMON expressed his intention of waiting for "further confirmatory evidence." Such evidence was soon forthcoming. The staff of the Fulham Hospital, against whom there had some allegation of slackness in respect of the comings goings of certain persons connected with the institu decided to put their house in order. Unfortunat however, for those who believed that the spread of infect was due solely to personal contact with the hospital inf tion, on the next occasion when the hospital was used small-pox isolation a precisely similar spread of infe tion occurred, and this was repeated, not once, b many times. As the distance from the hospita decreased, even so did the incidence of small-pox upon the houses. The recurrence, indeed, was so marked that it was eventually decided to treat no more acute small-pox cases within the metropolitan area, and subsequently the metropolitan small-pox cases were banished to the hospital ships. Thereupon the area around the London hospitals showed no special incidence of small-pox, and all opportunities for further illustrating the truth of Mr. POWER'S thesis, in so far as London was concerned, came to an end. As, too, there was not much small-pox in the country the opponents of the thesis could still point to certain provincial hospitals and allege that there was no evidence of harm from their operations. But in 1887–88 the Sheffield epidemic occurred, and here again there was the same graduated incidence around the small-pox hospital, albeit the circumstances were regarded as too complicated to justify the inference that such incidence had not been by personal contact. In 1892 and 1893, however, there was an outbreak of small-pox at Oldham, and Dr. J. NIVEN, now medical officer of health of Manchester, who was then the medical officer of health of Oldham, came to the conclusion that the theory of aerial convection alone was capab of explaining the incidence of the disease in th neighbourhood of the hospital. Similar occurrences too place at Warrington, Bradford, and other places, wher again aerial convection was thought by the medical officers of health to be the only adequate explanation of the peculiar distribution of the disease. But still the opponents of the views pointed to the hospital ships, where they affirmed there was no evidence of harm. It is important, however, to note that there are but few houses in the immediate neighbourhood of the ships, and that the constant current of air, which the rise and fall of the tidal waters of the Thames must produce, renders the circumstances somewhat unusual. Moreover, the hospital ships were hardly likely to be the cause of mischief when they contained no small-pox. But these facts notwithstanding, there have been ugly rumours afloat in the basin of the Thames for several years as to the excessive incidence of small-pox in the vicinity of the ships, and at last the circumstances necessary to throw more light on the matter have occurred in the shape of crowded hospital ships, small-pox of the necessary type, and a county medical officer of health capable of collecting and marshalling the facts. The xtremely interesting but somewhat disquieting paper midwives, especially for restricting such practice to normal cases.

The rules of the Midwives Board should be subject to the approval of the General Medical Council.

Provision should be made by Act of Parliament for reimbursing the General Medical Council for any expenditure which they may incur in performing their duties under the Act.

The conditions under which licences to midwives are granted should include satisfactory evidence of character as well as of training and experience in the conduct of natural labour and in the after-care of lying-in women and newly-born infants.

Provision should be made securing that the midwife in cases of abnormality shall seek qualified medical assistance.

On a previous occasion when we published this summary we received from Mr. HEYWOOD JOHNSTONE, who is among the most eloquent and fair-minded supporters of the measure, a letter referring us to Clause 2 (2) and Clause 4 (1) of the Bill as proofs that the views of the General Medical Council were safeguarded in the proposed litigation. But Clause 2 (2) of the 1900 Bill has been modified so that unlicensed practice of midwifery for gain carries no penalty. And Clause 4 of the 1900 Bill is the clause the whole significance of which has been altered by the substitution of the Privy Council for the General Medical Council. So that it would seem that the promoters of the measure now before Parliament cannot pretend that their Bill satisfies the deliberate and expressed opinion of the General Medical Council—the governing body of the medical profession. And we can assure them that their Bill is equally objectionable to the medical profession at large.

◆

# The London Water Bill.

A BRIEF abstract of the London Water Bill was given in THE LANCET on Feb. 8th, p. 392, and in our remarks on the measure in a leading article at p. 384 we suggested that at first sight the Bill appeared to be an "'honest endeavour' to disembarrass the Local Government Board of some of the most useful and the most arduous of its present duties." A consideration of all the facts of the case confirms and strengthens this view, and leads us to point out that we do not consider the measure to be one which merits the support of those interested in the public health of the citizens of London. The responsibility of the President of the Local Government Board in the matter of the water-supply of London would practically cease if the Bill were passed, and he might congratulate himself that the matter was "finally settled" as far as he was concerned. But a responsibility, of the weight of which they are carefully kept in ignorance, would be shifted on to the shoulders of the London ratepayers. A Water Board with tied hands would be called into being. The board would be compelled by the very terms of its creation to buy the undertakings of the present metropolitan water companies. Does Mr. LONG seriously believe that the inhabitants of "Water London" wish to buy these businesses? If so surely he might allow his popularly elected Water Board to decide the matter as to whether purchase would be wise or not in the interests of its constituents. When we congratulated Mr. LONG on the ability he displayed in the speech in which he introduced his Bill into Parliament, we pointed out that he brought forward no serious arguments in favour of purchase of the present water businesses. He left his political opponents to attack the measure, which he expected would receive the general support of his own party, although he had previously said at a municipal-political "Smoking at home" that he thought that the Bill might not altogether please the London people in whose interests it was nominally brought forward.

There are certain obvious arguments in favour of the Bill, many of which will be found in the columns of our contemporary the *Spectator*. Briefly, it is urged in favour of purchase of the companies' undertakings that the dividends of the companies are likely to increase and that "therefore the companies were an adversary whom it was eminently expedient to agree with quickly." There are facts which point in the opposite direction. Enormous outlays will immediately be required to place and to keep the existing undertakings in an efficient state. Most of the facts proving this are already known to our readers, for we have more than once insisted upon them, but as they bear directly on the advisability of purchase it may be well to recall three of them :—

1. One of the companies has insufficient sources of water to supply its customers.
2. Several companies have at present inadequate provision for the storage and efficient filtration of the water which they distribute.
3. Constant water service is not given to all those who have the right to demand it.

It is, moreover, certain that an enormous outlay will soon be required to obtain increased supplies of water. The exact amount available from existing sources is not accurately known, because information has, as far as possible, been withheld by the companies which have declined to give particulars in regard to the water levels in their wells, or in regard to the effects which have been caused by persistent depletion of the underground water. It is, however, well known that evidence given before the Balfour Commission has turned out to be erroneous and that the amount of water which was stated to be available cannot be obtained. This matter was fully dealt with in the report of THE LANCET Special Commission on the Metropolitan Water Supply[1] and it need only be said now that the Balfour Commission was obviously misled by evidence which was not in accordance with facts. There can be no reasonable doubt that although some of the present sources of supply are failing the demand for water is increasing and will increase. In this matter the municipalisation of London will have a great effect. The reconstituted City of Westminster and the metropolitan municipalities have, as yet, hardly had time to get into thorough working order, or even, perhaps, to realise fully the greatness of the work which is before them. The City of London proper represents an ancient civilisation which is in thorough working order. Its cleanly streets are washed daily. The streets in the outside municipalities are still to a great extent unwashed. It is not likely that the people will much longer tolerate this state of things. It is certain that a very largely increased amount of water will be used daily for municipal purposes throughout "Water London." This will necessitate a corresponding increase in the amount distributed, but it present moment, his advice on all matters connected with its hygienic requirements should be of the greatest value to the architect. He will advise on questions of air-space, ventilation, drainage, and the means for the disposal of solid refuse from the wards. The last-named is a matter of peculiar moment in a hospital because of the infective character which such refuse often possesses, and which renders its retention in the vicinity of the patients a serious danger. Another of his duties will be that of frequent inspection of all drains and other sanitary appliances about the hospital. The ease with which these may become inefficient in a building occupied by a large number of persons is notorious. He may also be called upon to advise, in consultation with the medical staff, upon the nursing of infectious cases with the view of minimising risks of infection. Questions of practical disinfection of all kinds will further fall with propriety within his province. Measures of isolation and quarantine, when infectious disease chances to break out amongst the patients, will also require his attention and advice All these things and many more will be demanded of a sanitary officer, and it is plain that functions of such vital importance can only be efficiently performed by one who enjoys special qualifications in public health, and who has acquired by actual experience in the routine working of a hospital an intimate acquaintance with the subject. It cannot well be denied that the practical efficiency of a hospital and the welfare of its patients depend so largely upon its hygienic conditions that the status of the officer responsible for them may justly be placed higher than it has been in the past. It is for this reason that we welcome the step about to be taken by the Belgrave Hospital for Children, for we believe that it is one fraught with the best possible consequences for the future of hospital sanitation

---

[1] THE LANCET, June 21st, 1900, p. 181.

## A GLIMPSE INTO THE NATURE OF THINGS.

THE momentous question, what is matter? has for long been put aside by many ardent investigators as probably for ever insoluble. But when we are told that we have actually touched the borderland where matter and force seem to merge into one another we may reasonably assume that we are on the eve of gaining a nearer insight into its nature. This was the subject which Sir William Crookes took the opportunity of discussing before His Royal Highness the Prince of Wales on the occasion of his formal admission to the Fellowship of the Royal Society on Feb. 6th. Sir William Crookes's declaration marks a very important epoch in the progress of science, and it was fitting that this epoch should have been associated with an interesting and historical Royal incident. The existence of a fourth state of matter has for a long time been indicated in radiant phenomena Sir William Crookes called it the "ultra-gaseous" state, and later "radiant matter," while more recently the latter phrase has given way in favour of the term "electrons" An electron is, so to speak, an atom of electricity which exists always in the presence of the atom of matter. The electron is the satellite of the particle which when liberated from it under the influence of electric discharge behaves not as a gas but more, as Sir William Crookes says, like a fog or mist, clinging to positively electrified bodies and thereby losing mobility and settling on the walls of the container if left quiet. In the radiant matter-tube, under the influence of the current the material atoms arrange themselves in groups, while the rushing swarms of electrons driven from the negative pole meet them. The effect of the bombardment is light and heat. The questions, what are x rays and what is radio-activity may soon in the light of these revelations receive a satisfactory answer. The basis of the electron is probably the same in all cases, the protyle of Crookes, from which the chemical atoms are assumed to be formed. A negatively charged chemical atom is one having a surplus of electrons, the number depending upon the valency, whilst a positively charged atom is one having a deficiency of atoms. Truly we have here a glimpse into the nature of things. Veil after veil is being lifted and, as Sir William Crookes said before the British Association at Bristol in 1898, the face of Nature grows more beautiful, august, and wonderful with every barrier that is withdrawn.

## SMALL-POX IN LONDON.

THE small-pox returns for the past week show but little improvement. On Saturday, Feb. 15th, 33 fresh cases were notified and removed; on Sunday, the 16th, there were 39 fresh cases; on Monday, the 17th, there were 71 fresh cases; on Tuesday, the 18th, there were 63 fresh cases; and on Wednesday, the 19th, there were 54 fresh cases.

## THE ETIOLOGY AND EARLY DIAGNOSIS OF GENERAL PARALYSIS.

DR. WILLIAM PICKETT opened an important discussion on the Etiology and Early Diagnosis of General Paralysis of the Insane at a recent meeting of the Philadelphia Neurological Society, an account of which appeared in the *Journal of Nervous and Mental Diseases* of New York for January, 1902. The observations of recent observers—notably Krafft-Ebing—had shown that an antecedent syphilitic infection could be ascertained in three-fourths of the patients examined, and that elderly general paralytics were immune to syphilitic infection. Dr. Pickett, basing his investigation on 149 cases of general paralysis admitted as patients to the Philadelphia Hospital, could only find signs of antecedent syphilis in 60 per cent. but he thought that the actual proportion of syphilitics was slightly higher and that most of the early cases were demented. In the discussion which followed Professor Charles K. Mills stated that an experience of 25 years in private practice combined with the study of the literature of the subject led him to conclude that from 85 to 90 per cent. of general paralytics had antecedent syphilis. Dr. F. X. Dercum said that the proportion of demented cases in early general paralysis was, in his experience, large—nearly as large as that given by Dr. Pickett and Professor Mendel. He did not believe that ther was any relationship between general paralysis and epileps and he denied any causal relation between alcohol and general paralysis. "Almost, if not all, male paretics," said Dr. Dercum, "drink to excess in the earlier period of their disease." He also pointed out that such patients were very prone to develop delusions of marital infidelity. Dr. Alfred Gordon referred to the almost invariable presence of congenital syphilis in juvenile paretics and cited the recently recorded observations of Regis, who in every one of five consecutive cases of juvenile paresis found congenital syphilis. In a discussion at the New York Medical Society[1] on the causation and early diagnosis of general paralysis Dr. Arthur Hurd of Buffalo stated that he found signs of antecedent syphilis in 68 per cent. of patients, but pointed to the fact that though syphilis was widely prevalent in Egypt and Japan paresis was rare in both countries. He argued that the overwork and keen stresses of western civilisation excited general paralysis in a brain weakened by syphilis and thought that in time to come the disease would increase in the two countries referred to. In America the disease was most common amongst military men, actors, stock-brokers, and men accustomed to mental overstrain, and rare amongst Quakers and the clergy. Dr. Dercum said that early diagnosis was important, the mistal made most often being to regard early general paralysi by Dr. J. C. THRESH which we publish in another part of the present issue unfolds the real story as to the influence of the ships. The map which accompanies the paper shows that on the Essex side of the ships there are practically no houses within the half-mile radius, but that the three-quarter mile radius embraces the hamlet of Purfleet, which, it must be noted, is divided into two portions, West and South. Confining our remarks mainly to the present epidemic a remarkable fact is brought out that up to Feb. 1st of this year there have been no less than 290 cases of small-pox in the Orsett Union, which is the Essex union nearest to the ships and which has a population of 33,721. In the whole of the rest of the county with a population of 782,700 there have in the same period been but 162 cases—i.e., the incidence on the population of the Orsett Union was 8·6 per 1000, as compared with 0·21 per 1000 on the rest of the county. The incidence on Purfleet, which is nearest the ships, was 88 per 1000, that on the remainder of the parish which comprises the hamlet 2·4 per 1000, and that on the remainder of the Orsett Union 2·8 per 1000—i.e., the nearer the population to the ships the greater the incidence. Now the prevailing wind, which was during the period in question north-west and west-south-west, blew over that portion of Purfleet known as South Purfleet, but very rarely over West Purfleet, and the bearing of this fact is shown in the incidence of small-pox on the South Purfleet population having been no less than 12·0 per cent., while that on West Purfleet was only 0·8 per cent. Such an incidence as the former is truly terrible to contemplate, and, as Dr. THRESH observes, there would at this rate have been in the London population over 500,000 cases within the last seven months. But even this does not complete the story, for the unvaccinated of South Purfleet have been laid low with merciless precision. There were in Purfleet 19 unvaccinated persons, of whom nine had had small-pox before the epidemic; of the remaining 10, no fewer than eight, or 80 per cent., have contracted the disease during the last seven months. No one who is at all familiar with the topography of the valley of the Thames near Dartford and of the rigid enforcement of the rule that no attendants at the ships shall visit Purfleet can do otherwise than agree with Dr. THRESH that personal infection from the ships is a very insufficient and, indeed, almost impossible explanation of this remarkable incidence of small-pox on the adjoining Essex coast.

---

[1] New York Medical News, Feb. 1st, 1902.

We have in the pages of THE LANCET always supported the view that aerial convection alone explains certain of the remarkable outbreaks which are liable to occur, under given atmospheric conditions, in the neighbourhood of small-pox hospitals or of institutions being used for the isolation of acute small-pox cases. And it seems to us that in the present instance Dr. THRESH's view that aerial convection has again been operative is the only explanation consistent with all the facts. Obviously air-borne infection and human intercourse are at times both operative, but it has to be borne in mind that the one does not exclude the other. There are some who regard the cases of small-pox in the Essex districts as due to *water-borne* infection from the ships, but bathing in the Thames at this season is not very common nor are the inhabitants of the districts involved so hard up for drinking-water that they must needs resort to the saline and sewage-polluted solution of the Long Reach. The revelations as to the incidence of small-pox in South Purfleet are extremely inconvenient, and one of their results is likely to be violent opposition to any proposals for the erection of small-pox hospitals. Another result should be the recognition of the fact that we cannot by isolation hope to get rid of small-pox. The remedy is ready to hand and consists in placing revaccination on the same basis as primary vaccination. With the German method we shall avoid small-pox outbreaks, but with primary vaccination alone we can never hope to do so.

# Annotations.

"Ne quid nimis."

## SANITARY OFFICERS FOR HOSPITALS.

THE authorities of the Belgrave Hospital for Children are about to appoint a sanitary officer to the hospital. The qualifications required for the office include the holding of a Diploma in Public Health, and its duties comprise, not only the supervision of all the sanitary affairs of the hospital, but also consultation with the medical staff in the event of the outbreak of any infectious disease in the wards. It is true that the institution of such an office on the part of the Belgrave Hospital is not an entirely new departure; we know of at least one large general hospital which for some 10 years past has had the services of a specially appointed officer of the kind, while one well-known special hospital utilises in the same way those of the medical officer of health of the district in which it is situated. The importance of sanitation in hospitals is such a commonplace that its determining conditions are apt sometimes to be forgotten. It is requisite, not merely that the original planning of the building should be as perfect as sanitary science can make it, but that, when in working order, constant supervision should be exercised in order that its hygienic arrangements should work smoothly and efficiently. The most elaborately designed system of ventilation may at times work imperfectly and the most perfectly constructed drains become blocked. Despite the best sanitation, infectious diseases are inevitably imported into a hospital from time to time, and the limitation of their spread demands the most anxious consideration. It may safely be asserted, without any disparagement of the marvellous advances in surgery and medicine which the last 20 years have witnessed, that sanitation has played an enormous part in reducing hospital mortality. Those who are sick, and especially the subjects of surgical operations, are abnormally sensitive to insanitary conditions of every kind, and though bacteriology has in part explained this it has by no means completely done so. The horrors of the older hospitals are known by repute only to the present generation, but though hospital gangrene and phagedæna are practically things of the past we cannot believe that even our best-equipped modern hospitals are altogether insusceptible of sanitary improvement. And it is to sanitary experts who are in constant touch with the practical working of hospitals—to men who can be held responsible for the occurrence of preventable disease amongst the patients—that we may most safely look for improvements in hospital hygiene. The functions which the sanitary officer of a hospital may be called upon to fulfil are numerous and we can touch on them but slightly. Where a new building is being constructed, as in the case of the Belgrave Hospital at the right breast diminished, but when the patient left the hospital slight induration in the upper and outer quadrant could still be appreciated. There had been no previous disease or injury of the breasts. In 1874 Leudet recorded five cases in which one or both breasts became tender and swollen in typhoid fever and showed inflammatory masses.[1] In all resolution occurred. Curschmann states that transitory swelling of the breasts at the height of the fever is not uncommon and may be overlooked as the patient does not complain.[2] The writers alluded to above have been able to find records of only four cases of suppurative mastitis in typhoid fever. In one described by Charlotte P. West there was a general pyæmic condition.[3] At the beginning of the third week both breasts became swollen and tender, possibly from hypodermic injection of saline solution. At the beginning of the fourth week localised dusky red swollen elevations were discovered in both legs, both arms, and both breasts. Those in the right leg, the left arm, and both breasts suppurated and healed after incision. Recovery followed. In 1891 Destrée reported two cases of typhoid fever in which an abscess developed in the right breast at the end of the third week, but the pus showed only staphylococci. The fourth case is reported by Capellari and is almost exactly parallel to the one described above A girl, aged 15 years, developed pain and swelling in the right breast in the fourth week. The temperature, which had become normal, assumed a septic type. The abscess was opened and recovery followed. No bacteriological examination was made. Capellari lays stress upon the age of the patient, believing that at puberty the rapid development of the mammary glands predisposes to inflammation. In one of the cases of suppurative mastitis quoted above it is stated that the preliminary swelling and tenderness of the breasts were thought to be due to the hypodermic injection of saline solution. It has been pointed out in THE LANCET[4] that the typhoid bacillus (which is usually present in the blood in typhoid fever) may be localised at the sites of injuries received during the fever. Further, the injury in one of the cases there described was due to the hypodermic injection of saline solution. Hence it may be fairly concluded that in the case now quoted this was the exciting cause of the suppuration.

## DEATH FROM FISTICUFFS.

THE coroner's jury at Hackney which recently inquired into the death of a man named Barnett and returned a verdict of "Death by misadventure" showed more good sense and discrimination than are always exhibited on such occasions. The deceased and a man named Smith had a quarrel originating in a discussion over the meaning of the word "punter," and the discussion of this somewhat trifling matter—which perhaps makes the prevalence of betting the originating cause of the tragedy—seems to have aroused considerable ill-feeling in the mind of Barnett. After some preliminary scuffling it was arranged that the two men should formally fight later in the day, Barnett throughout being the aggressor and Smith showing himself unwilling to continue the quarrel. In the end, however, Smith proved himself the better man with his fists, and, after what appears to have been a perfectly fair fight in the presence of a number of his fellow workmen, Barnett received a blow on the jaw which rendered him insensible. Very soon afterwards he died. The medical evidence was to the effect that Barnett had been severely punished about the head and face and that the blow on the jaw had probably caused concussion of the brain, while the fall had ruptured a blood-vessel on the brain. In such circumstances men before now have been committed for trial for manslaughter and indicted for that they did "feloniously kill and slay" their opponents. The verdict of the jury, found under the direction of Dr. Wynn Westcott, coroner for North-east London, seems to recognise the fact that if rough men choose to settle their disputes with their fists a fatal occurrence is not necessarily chargeable against the survivor as a crime. It is for the pistol, the knife, and the attack by an organised gang as modes of settling quarrels between men or boys that the criminal law should be set in motion. The fist, as the occurrence we are commenting on shows, may, guided by an unhappy chance, be a deadly weapon when wielded against a man possibly not in the best physical condition and not trained to receive or to avoid blows dexterously; but the annals of the prize-ring are sufficient to show the extraordinary amount of battering with the bare fist that the head and body of a man will take without injury when he is in sound health, practised, perhaps, to avoid the more dangerous strokes, and inured to receive blows as well as skilled to deliver them. It no doubt weighed with the Hackney jury that the man whose fate was in its hands had not been the aggressor but must be taken to have had no choice between submitting to be bullied and fighting in self-defence.

## THE AUDITORY APPRECIATION OF MOSQUITOES.

THE science of electricity has within the last quarter of a century made enormous strides, and this force is now utilised in America to put what is alleged to be a painless end to a criminal existence. But the idea of destroying mosquitoes by this means is a novel one. It seems, however, according to a paper on the structure and biology of anopheles which has been contributed to the current number of the *Journal of Hygiene* by Dr. George Nuttall and Mr. Arthur Shipley, that the mosquito is peculiarly susceptible to sounds of a certain character. It is stated, for instance, that persons are more liable to be bitten when engaged in conversation than when silent, and that when a stringed instrument is played the mosquitoes in the room become extremely active, and those outside enter the room through the open window. So, too, when music is played in the open, whether in the dark or in presence of a lamp, the mosquitoes tend to congregate around the performer. It is also reported by an electrical engineer that when he was engaged on some experimental work on harmonic telegraphy he found that when the note given out by the instrument was raised to a certain pitch all the mosquitoes, both those inside and those immediately outside the room, crowded together near the apparatus. The ingenious engineer converted the apparatus into a fly-catching machine by covering it with fly paper, and having attracted and captured the insects proceeded to electrocute them. In this connexion it may [illegible]ed that towards the end of last year a letter [illegible] in the *Times* from Sir Hiram S. Maxim in which he narrates that while erecting an electric light apparatus at Saratoga Springs, New York, one of the lamps, which was of a somewhat peculiar type, gave off a constant musical note. One evening on examining this lamp he found that everything in the immediate vicinity of the box below the globe which was emitting the sound was covered with mosquitoes. An examination led to the discovery that all were males, and this in spite of the fact that there was in the neighbourhood an enormous preponderance of females. Sir Hiram Maxim states in graphic language that "when the lamps were started at the beginning of the evening every male mosquito would at once turn in the direction of the lamp and, as it were, face the music, and then fly off in the direction from which the sound proceeded." That the male mistook the buzzing of as neurasthenia. "The paralytic," said Dr. Dercum, "seldom came of himself to consult a physician; he was brought by his friends, and unlike the neurasthemac [or hypochondriac] he had no long story to tell." The paretic in the early stages of his disease was liable to lapses of memory, of decency, and of ability for work. The neurasthemac after brief and light sleep had a wakeful morning, felt depressed on rising, and did not care to face the day, while he felt at his best in the evening. The paretic, on the other hand, tossed in bed with little or no sleep during the night and only slept a little in the morning. He felt at his best in the forenoon and was quite exhausted in the evening. Dr. Charles Wagner said that general paralysis had increased steadily in America since 1850, being first noticed in the period 1850 to 1860. At present 10 per cent. of all patients in American asylums were paretics. It was especially prevalent among native born Americans, whereas *the alien population was more liable to* develop psychoses. Dr. Edward Cowles declared that anti-syphilitic treatment did not benefit paretics and argued that the disease was a toxæmia like myxœdema.

## THE WORKING OF PLAGUE MEASURES IN INDIA

THOSE of our readers who have been in the habit of referring to the "Notes from India" furnished by our special correspondent will have been enabled to keep themselves fairly abreast with the progress of plague in that country. From the increase of the plague mortality which has been taking place of late and the high general death-rate of Bombay it may safely be inferred that the city of Bombay will not escape the usual epidemic rise of the disease which, according to past experience, occurs at this season. This very naturally has *given rise to increased* vigilance and efforts on the part of Dr. J. A. Turner, the health officer, and the medical and municipal authorities concerned. The organisation and methods of procedure are fully set forth in some articles which appeared in the *Times of India* of Feb. 1st. It goes without saying that all systems of sanitary organisation and public health measures must be circumscribed within the limits of what is practically attainable and their methods of working should be such as are not calculated to arouse a general spirit of antagonism on the part of those to whom they have to be applied. If this be the case even among educated people who are willing to make some sacrifices and to submit to personal inconvenience in the public interest it is still more so in the case of Oriental races who are tied and bound by religious and social traditions and who are intensely conservative where these are concerned. The aim in view *is not so much* perhaps, what is sound and logical in theory or what might be applicable to a small and relatively isolated population where all the conditions are known—like that of a rural village *for example*. Large and populous cities and towns have to be dealt with where the health conditions are unfavourable and complicated, and preventive measures cannot be pushed to a logical conclusion without causing much discomfort and even hardship. What seems to be the most suitable course under such circumstances is the organisation of some good, simple, and uniform sanitary system on a practical working basis, the establishment of some method for the early notification of disease and death together with arrangements for promptly evacuating infected and overcrowded localities and buildings by the selection and provision of sites and encampments suitable for immediate occupation. Such measures will not only allow of the removal of people in anticipation of an outbreak and the thinning of overcrowded localities, but will permit also of a thorough disinfection of the evacuated houses being carried out and of their being subsequently ventilated and freely exposed to the air and sunshine. Owing to the action of the health officer and the local authorities in Bombay there seems to be every prospect of the suitable machinery being present and ready for carrying out these objects. We need scarcely add that, as far as practicable, recourse should also be had to the use of Haffkine's method of preventive inoculation *against plague*.

## CHELSEA CLINICAL SOCIETY

THE annual clinical debate of this society is fixed for March 11th and 18th next at the Jenner Institute of Preventive Medicine, Chelsea Gardens, *Grosvenor road*, S.W., at 8.30 P.M. The subject selected for discussion is "Cancer—its Nature, Origin, and General Principles of Treatment." The debate will be opened by Dr. J. F. Payne and full particulars will be shortly announced. The debate will be open to all members of the medical profession.

## THE CASE OF THE LATE MR. R. B. ANDERSON

MR. WALTER MONNINGTON, the honorary secretary of the fund in aid of the widow and children of the late Mr. R. B. Anderson, F.R.C.S. Eng., writes to us as follows:—

> The committee formed to appeal for aid for the widow and sons of the late Mr. R. B. Anderson, F.R.C.S. Eng., beg to announce that the subscriptions now received amount in all to £202 5*s.* 6*d.* and to request intending subscribers to kindly forward their donations *at once* marked "For the Anderson Fund" to the manager of the Union Bank of London, Chancery-lane, London, as it is definitely proposed to close *the account on the 28th inst.* A *strong hope was entertained of collecting at least* £500—the sum, it might well be remembered, fixed by the jury by their verdict in Mr. Anderson's favour in "Anderson *v.* Gorrie and Others." It is still desired that the £202 now in hand may be largely augmented before the fund closes on the last day of this month.

We need not again expatiate upon Mr. Anderson's wrongs or upon the needs of his widow and children. It is not a large sum which is wanted now—only £300. Surely those medical practitioners who have not yet subscribed—there are many such—will not hesitate in making up the comparatively small sum required.

## TYPHOID MASTITIS

IN the *American Journal of the Medical Sciences* for December, 1901, Dr. I. Davis, jun., Dr. H. S. Patterson, and Dr. A. W. Hewlett have published a case of this very rare complication of typhoid fever. A woman, aged 34 years, was admitted to hospital on May 25th in the third week of an attack of typhoid fever. The temperature was 105·1°, rose spots were present, and Widal's reaction was obtained, but blood cultures made on May 27th and 31st did *not yield* the typhoid bacillus. On June 9th, the thirty-sixth day of the disease, the temperature became normal. Three days *later the patient complained of pain in the left breast.* On June 14th the breast was swollen, a hard and tender lump was felt on its outer side, and the axillary glands were enlarged and tender. On June 15th the right breast was also tender. Lead and opium compresses were applied and the breasts seemed to improve, but the temperature, which began to rise on the 15th, showed wide daily oscillations of the septic type between 99° and 102°, and not the "staircase" character of a typhoid relapse. On the 20th the swelling and tenderness of the left breast had become much more marked and involved the two upper and the outer lower quadrants. The skin was freely moveable and the nipple was not bound down. On the 24th the temperature reached 104° and fluctuation was detected. Under chloroform an incision was made and 150 cubic centimetres of thick pus containing the typhoid bacillus in pure culture were obtained. The abscess cavity consisted of many loculi which were broken up with the finger. After the operation the temperature at once fell to normal and healing was uninterrupted. The swelling in the a minute or two he commenced to cry and complained of abdominal pain. This occurred on several occasions, and as he was a frank and manly little fellow no doubt was entertained of the reality of the pain. Exploration was therefore performed. The umbilicus was included in an elliptical incision and removed in its entire thickness. No adhesion or other abnormality could be found. The ascending colon was drawn out of the wound until the appendix appeared. Suspicion fell upon the latter which was very long and tortuous and appeared to be distended. It was removed and the abdomen was closed. Recovery was uneventful and the boy was completely and permanently relieved. The lumen of the appendix was dilated, the mucous membrane was thickened and congested, there was considerable excess of lymphoid tissue, and the cavity contained a large number of thread-worms. On inquiry it was ascertained that all the children of the family, of whom the patient was the eldest, were infested with thread-worms.

## THE DANGEROUSLY INFLAMMABLE NATURE OF CELLULOID

Despite the fact that quite a crop of serious accidents have been recorded for the past 10 years in The Lancet arising from the use of celluloid ornaments little or nothing appears to have been done to render celluloid less fiercely inflammable In an article printed elsewhere in our present issue Professor Ogston records some further cases illustrating the dangers of this substitute for ivory and horn and these cases afford a complete endorsement of all that we have said in our columns upon this subject from time to time. Although he refers to a number of instances of burns due to celluloid which have been published in The Lancet as well as to some experiments which our laboratory commissioners conducted in 1892 in regard to the inflammability of celluloid he omits to mention the experiments which were made by our commissioners in 1898—experiments which are in striking accord with those which Professor Ogston now records. In The Lancet of March 5th, 1898, p. 661, will be found the results of some experiments in which the danger of placing a celluloid comb in the hair was amply demonstrated. The actual experiments consisted in placing a celluloid comb in position in a wig at varying distances from a glowing fire and the results were absolutely convincing as to the probability of most serious consequences ensuing to the wearers of these celluloid ornaments. Further, it was found that a curling iron heated to the temperature necessary for curling purposes would readily start the evolution of dense and highly inflammable fumes if brought in contact with a celluloid comb or hairpin. The proximity of a naked light adds to the danger enormously, for the fumes of celluloid will ignite fiercely at some considerable distance from the flame. Later, we demonstrated the danger of exposing celluloid toys in shop-windows close to electric lamps. Professor Ogston suggests that all celluloid articles for personal wear should have the word "ignitible" conspicuously imprinted upon them. We suggested, now nearly four years ago, that the manufacturers of these dangerous articles should be compelled to stamp plainly upon them the words "highly inflammable." The danger is no imaginary one. We remember an instance in which a gentleman with a lighted cigar in his mouth was playing upon an "American organ" furnished with celluloid keys Of course, he was wrong to be smoking at such a moment, and he was convinced of this by the fact that when some red hot ash dropped upon the keys they instantly burst into fumes and flame which could only be extinguished with the greatest difficulty. Surely some means could be devised to impregnate the material with an inert or deterrent substance and so to render celluloid less liable to decomposition and consequent fierce ignition.

## THE GENERAL MEDICAL COUNCIL.

A special session of this Council will begin on Tuesday, Feb. 25th, at the office of the Council, 299, Oxford-street, at 3 P.M., under the presidency of Sir William Turner. The question at issue between the Council and the Royal Colleges of Physicians of London and Surgeons of England will constitute the business of the session.

Mr. Pearce Gould delivered the first of his Lettsomian Lectures before the Medical Society of London on Monday, Feb. 17th, his subject being "Certain Diseases of the Blood-Vessels." We shall publish these lectures in full in our columns.

His Highness the Khedive has bestowed on Mr. Harry Crookshank (Pasha), F.R.C.S. Edin., the Grand Cordon (first class) of the Imperial Order of the Medjidie in recognition of his signal services in Egypt.

In a Convocation held on Feb. 18th the University of Oxford conferred the degree of Hon. M.A. upon Mr. Alfred Winkfield, F.R.C.S. Eng. Mr. Winkfield is medical officer of health of Oxford.

# Looking Back.

FROM

## THE LANCET, *SUNDAY, FEB.* 22, 1824.

### HOSPITAL REPORTS.

### Guy's Hospital, Feb. 21.

### PHYSIOLOGICAL EXPERIMENT.

The following curious experiment has been lately tried by Dr. Blundell, lecturer on midwifery at this hospital. This gentleman opened the common carotid of a dog, and allowed the artery to bleed till the animal appeared dead; when Dr. B. immediately injected into the jugular vein, the blood that had been drawn off, which had the effect of resuscitating the dog. From the result of this experiment, Dr Blundell infers that when the vital powers appear to be extinguished in a woman during parturition from uterine hæmorrhage, there is a chance of restoring animation by the immediate injection of blood into the jugular vein. Whether the blood to be injected is that of the patient herself, or of some animal which is to be killed for the purpose, we are not exactly certain, but we believe the former.

### COLLEGE of PHYSICIANS.

We have received communications from some members of this body, complaining of the inequality that exists between the privileges of the Licentiates and Fellows of the College. and requesting us to take up the subject. The fact is, that the regulations of the College complained of aim at this one object, viz. the keeping up an aristocratic distinction between the Graduates of the English Universities and those educated elsewhere, without any reference to the respective merits of the different individuals. We shall therefore feel it our duty, at some future time, to comply with the request.

### EFFICACY OF THE SULPHATE OF QUININE IN AGUE.

Dr. Michaelis, of Berlin, has recently had an opportunity of trying the efficacy of this new medicine, in a great number of cases of intermittent fever, which has chiefly attacked children in a particular district. He has given it in doses of three grains to children, during the remission, with the greatest success,—this quantity being sufficient to prevent a return of the fever.—*Journal der Chirurgie von Grafe und Walter.*

the instrument for the buzzing of the female is probable, seeing that the notes emitted were practically identical Here, then, is a new phase of sexual selection which is likely in the hands of the electrician to lead rather to the extinction than the perpetuation of the species But doubtless there would arise some discriminating males who, refusing to be attracted to electrocution, would survive to impregnate the superabundant females Sir Hiram Maxim suggests an interesting experiment "If," he says, "you obtain a tuning fork which emits a note as near to that of a female mosquito as possible [and strike this fork within 20 feet of a male mosquito he will at once turn about, face the music, and erect the two little feathers of his head, something after the manner of a cockatoo"

## THE DISTRIBUTION OF PLAGUE

As regards Egypt, during the week ending Feb 9th 8 cases from plague and 8 deaths from the disease have been reported from all Egypt. 4 cases and 6 deaths occurred at Tantah 3 cases and 1 death at Abousir, and 1 case and 1 death at Kafr Enan near Ziftah Tantah has shown a marked improvement during the week, as only 4 of the cases mentioned above were fresh cases, 2 being admitted to hospital and two being found dead out of hospital As regards The Mauritius a telegram from the Governor received at the Colonial Office on Feb 14th states that for the week ending Feb 13th there were 15 cases of plague, of which 9 proved fatal

## SOME DISADVANTAGES ATTENDING ELECTRIC SYSTEMS

WE anticipated at the time when the electric underground railways were started in London that sooner or later, owing to their peculiar construction, better means would have to be devised for providing these 'tubes" with fresh air We were pretty freely criticised by those responsible for the construction of these railways for entertaining such "exaggerated" notions We are face to face with the fact now that the air at least of one "tube —namely, the Central London Railway—is fœtid and poisonous Numerous letters have appeared recently in the daily press complaining of this objectionable and growing characteristic, so that, in spite of the undoubted convenience of the "tube, many persons are being deterred already from travelling by it on account of the nauseating effect of the air in the tunnels and even at the booking offices To not a few the preliminary greeting of bad air as each lift discharges its load at the ground level is enough There is no doubt that the management of this railway is face to face with a difficulty which, in the interests of the public and therefore of themselves and their shareholders, must be overcome Under the present conditions, and especially in a time of epidemic, the tube may easily become a disease disseminating channel There can be no difficulty in providing a remedy—namely, by pumping fresh air through the tunnels We are glad to note that some efforts are being made to avoid the possibility of danger connected with short circuiting on electric railways It appears however that at present there seems to be no sure way of preventing short circuiting, so that the next best thing is to provide against its effects when it happens Insulation apparently may be perfect at the start but there are countless agencies which conspire to break it down, at any rate as it is carried out at the present time There is no doubt that for their own sakes those whose business it is to distribute the electric current would prefer to do it safely and free from the chances of short-circuiting Short circuiting is a source of danger to the public and a decided loss to the electric companies We cannot help thinking, however, that in view of so many short circuiting occurrences electrical engineers must own that it is a contingency which baffles them This week, at about 10 A M on Monday, an accident occurred in connexion with the electric lighting cables close by our offices By some it was attributed to the upsetting of a spirit lamp during repairs, although what followed was analogous to previous outbreaks of fire in electric boxes in which short circuiting was the undoubted cause Dense black fumes suddenly belched forth from a "box" in the pavement just outside the Adelphi Theatre and later the dense fumes were accompanied by fierce flames several feet high The event was evidently sufficiently alarming to bring a large number of fire engines upon the spot within a few minutes of the outbreak Subsequently the outbreak was subdued by choking the cavity with sand and closing the crevices with sacking We noted that the intelligence of the firemen was displayed in the fact that not until the current was cut off was water poured into the hole, otherwise it is possible that an inflammable mixture would have been generated and a serious explosion might have ensued No great damage appeared to have been done and by prompt work the company was able to supply the current to its consumers again before dark It was fortunate that the accident did not happen on a dark foggy day We still believe that short circuiting would happen less frequently if greater and better attention were given to the requirements of efficient insulation

## THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE following resolution of a special committee was unanimously adopted by the Council of the Royal College of Surgeons of England on Feb 13th, and at an extraordinary meeting of the Comitia of the Royal College of Physicians of London on Feb 18th, namely —

> This Committee recommends the two Royal Colleges to consider and develop a scheme for investigation into the causes, prevention the treatment of cancer and that for this purpose delegates be appointed by the two Royal Colleges (who shall have power to add to their number) to draw up a detailed scheme.

In pursuance of this resolution the following delegates were appointed to draw up a detailed scheme for systematic investigation into the causes, prevention, and treatment of cancer, viz —As representing the Royal College of Physicians of London Sir William Selby Church, Bart, President, Sir William H Broadbent, Bart, K.C V.O ; Dr P H Pye Smith Dr Whipham, Dr Payne, Dr J Rose Bradford and Dr J F W Tatham As representing the Royal College of Surgeons of England Mr H G Howse, President, Mr I Langton Mr H Morris, Mr H T Butlin, Mr W Watson Cheyne, C B, and Mr R. J Godlee

## APPENDICULAR COLIC FROM THREAD-WORMS IN THE VERMIFORM APPENDIX.

IN the *Intercolonial Medical Journal of Australasia* for December Mr R Hamilton Russell has recorded a case of this rare and interesting condition A boy, aged nine years, was taken to hospital with the following history From two to three years before he began to complain of abdominal pains which appeared to be excited or aggravated by going up and down stairs Sometimes the pains were so severe that he was carried by his companions He was also frequently seized with abdominal pains when in bed and was sometimes awakened by them. He was unable to run about and to play with his schoolfellows and a day rarely passed without an attack of pain which he always referred to the umbilicus, where there was a small hernia He was admitted with a view to operation on the latter but as he had no attacks of pain in hospital the operation was not performed Seven months later he was readmitted with the history that the symptoms had become worse There was no tenderness in the region of the appendix, but after the abdomen had been under examination for disabled from work, or who are at hospital or in prison, are taken in here to be cared for and protected by the State until their parents are in a condition to receive them again. Your indefatigable guide leads you to the receiving-room where you see the latest of these little visitors just brought in and witness their delight as a necklace of blue-and-red beads is clasped round the neck of each. This necklace is the mark of the child's identity. To it is suspended a small silver pendant stamped with a number which corresponds with a similar number kept in the register. Your guide takes you through the dining-rooms, kitchens, gardens, and hospitals, and convinces you, by her appearance, by her words, and by what she shows you, of the care and devotion with which the institution provides for the welfare of its adopted children.

Of the children permanently abandoned there is not much to be seen. These children, mostly babies, are removed as soon as possible to the country and seldom remain for more than a day or two at the town house. What is to be seen of them, however, is a wonderful sight. You find them in a large and airy room—long rows of babies in cots, babies being washed, dressed, fed—baby jargon, baby lamentation filling the air; stacks of baby garments and pyramids of baby bottles standing about the place. Most marvellous amongst them are the newcomers, identical in form, size, raiment, and expression—laid out on their backs in a row, contorting their foolish faces, and waving their comical limbs. They are awaiting baptism. Side by side they lie, indifferent to the birthright which they have lost, full of beseeching demands which they cannot utter. But in France all voices speak for them.

# THE MIDWIVES BILL, 1902.

THE following is the text of the Midwives Bill, 1902, which was issued on Feb. 13th. It is prepared and brought in by Lord Cecil Manners, Mr. Tatton Egerton, Mr. Schwann, Mr. Parker Smith, Sir Savile Crossley, Mr. Eugene Wason, Mr. Tennant, and Mr. Heywood Johnstone.

## MIDWIVES BILL.

### ARRANGEMENT OF CLAUSES.

Clause.

1. Short title and commencement.
2. Certification.
3. Provisions for existing midwives.
4. Constitution and duties of the Central Midwives Board.
5. Fees and expenses.
6. Midwives roll.
7. Appointment of secretary and supplemental provision as to certificate.
8. Local supervision of midwives.
9. Delegation of powers to district councils.
10. Notification of practice.
11. Penalty for obtaining a certificate by false representation.
12. Penalty for wilful falsification of the roll.
13. Prosecution of offences.
14. Appeal.
15. Expenses of local supervising authority.
16. Act not to apply to medical practitioners.
17. Extent of Act and action by English Branch Council.
18. Definitions.

### A BILL TO SECURE THE BETTER TRAINING OF MIDWIVES AND TO REGULATE THEIR PRACTICE.

Be it enacted by the King's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. *Short title and commencement.*—This Act may be cited as the Midwives Act, 1902. It shall, except as otherwise provided by this Act, come into operation on the first day of April, one thousand nine hundred and three.

2. *Certification.*—(1) From and after the first day of January, one thousand nine hundred and five, no woman shall be entitled to take or use the name or title of midwife (either alone or in combination with any other word or words), or any name, title, addition, or description implying that she is certified under this Act, or is recognised by law as a midwife unless she be certified under this Act.

(2) Any woman who, after the first day of January, one thousand nine hundred and five, not being certified under this Act, shall take or use the name of midwife or any other such name, title, addition, or description as aforesaid, shall be liable on summary conviction to a fine not exceeding five pounds.

(3) No woman shall be certified under this Act until she has complied with the rules and regulations to be laid down in pursuance of this Act.

(4) No woman certified under this Act shall employ an uncertified person as her substitute.

(5) The certificate under this Act shall not confer upon any woman any right or title to be registered under the Medical Acts or to assume any name, title, or designation implying that she is by law recognised as a medical practitioner, or that she is authorised to grant any medical certificate, or any certificate of death or of stillbirth, or to undertake the charge of cases of abnormality or disease in connexion with parturition.

3. *Provision for existing midwives.*—Any woman who within two years from the date of this Act coming into operation claims to be certified under this Act shall be so certified provided she holds a certificate in midwifery from the Royal College of Physicians of Ireland, or from the Obstetrical Society of London, or such other certificate as may be approved by the Central Midwives Board, or produces evidence satisfactory to the Board, that at the passing of this Act she has been in *bonâ-fide* practice as a midwife and that she bears a good character.

4. *Constitution and duties of the Central Midwives Board.*—On the passing of this Act the Lord President of the Council shall take steps to secure the formation of a Central Midwives Board, which shall consist of—

(1) Four registered medical practitioners—one to be appointed by the Royal College of Physicians of London, one by the Royal College of Surgeons of England, one by the Society of Apothecaries, and one by the Incorporated Midwives Institute;
(2) Two persons (one of whom shall be a woman) to be appointed for terms of three years by the Lord President of the Council; and
(3) One person to be appointed for a term of three years by the Association of County Councils.

After two years from the commencement of this Act the members appointed under sub section (1) shall retire, but shall be eligible for re-appointment annually. Any vacancy occurring by resignation or death shall be filled up in the case of a member appointed under sub-sections (1) and (3) by the body which appointed him, and in the case of a member appointed under sub-section (2) by the Lord President of the Council.

The duties and powers of the Board shall be as follows:

I. To frame rules, subject to the approval of the Privy Council, after consultation with the General Medical Council,
  (*a*) regulating the issue of certificates and the conditions of admission to the roll of midwives;
  (*b*) regulating the course of training and the conduct of examinations;
  (*c*) regulating the admission to the roll of women already in practice as midwives at the passing of this Act;
  (*d*) regulating, supervising, and restricting within due limits, the practice of midwives;
  (*e*) deciding the conditions under which midwives may be suspended from practice;
  (*f*) defining the particulars required to be given in any notice under *Section 10 of this Act*.
II. To appoint examiners.
III. To decide upon the places where, and the times when, examinations shall be held.
IV. To publish annually a roll of midwives who have been duly certified under this Act.
V. To decide upon the removal from the roll of the name of any midwife for disobeying the rules and regulations from time to time laid down under this Act by the Central Midwives Board, or for other *misconduct, and also to decide upon the restoration* to the roll of the name of any midwife so removed.
VI. To issue certificates.

And generally to do any other act or duty which may be necessary for the due and proper carrying out of the provisions of this Act.

5. *Fees and Expenses.*—There shall be payable by every woman presenting herself for examination or certificate such fee as the Central Midwives Board may, with the approval of the Privy Council, from time to time determine, *such fee not to exceed the sum of 10s.* All such fees paid by midwives in practice at the passing of this Act and by candidates for examination shall be paid to the Central Midwives Board. The said Board shall devote such fees to the payment of expenses connected with the examination and certificate and to the general expenses of the Board. The Board shall, as soon as practicable after the thirty-first day of December in each year, publish a financial statement made up to that date, and certified by a chartered accountant as correct, showing the receipts and expenditure, including liabilities of the Board during the year. *The Board may apportion* between the councils of the several counties and county boroughs any balance against the Board shown in the financial statement in proportion to the number of midwives who have given notice during the year of their intention to practise in those areas respectively, and may recover from the councils the sum so apportioned.

6. *Midwives roll.*—There shall be a roll of midwives containing

(1) The names of those midwives practising at the date of the passing of this Act who have been certified under this Act;
(2) the names of those not already in practice as midwives at the passing of this Act, but who have been certified under this Act.

The entry on the roll shall in every case indicate the conditions in virtue of which the certificate was granted.

7. *Appointment of secretary and supplemental provision as to certificate.*—The Central Midwives Board shall appoint a secretary who shall be charged with the custody of the roll, and every person so appointed shall be paid such salary as the Board shall think fit, and shall be removable at the pleasure of the Board.

A copy of the roll of midwives purporting to be printed by the authority of the Board or to be signed by the secretary to the Board shall be evidence in all courts that the women therein specified are certified under this Act; and the absence of the name of any woman from such copy shall be evidence, until the contrary be made to appear, that such woman is not certified under this Act. Provided always, that in the case of any woman whose name does not appear in such copy, a certificate under the hand of the secretary of the entry of the name of such woman on the roll shall be evidence that such woman is certified under this Act.

8. *Local supervision of midwives.*—Every council of a county or county borough throughout England and Wales shall, on the commencement of this Act, be the local supervising authority over midwives within the area of the said county or county borough. It shall be the duty of the local supervising authority—

(1) To exercise general supervision over all midwives practising within their area in accordance with the rules to be laid down under this Act.
(2) To investigate charges of malpractice, negligence, or misconduct

# FOUNDLING CHILDREN IN FRANCE.

By CHARLES GORING, M.B., B.Sc. LOND.

> "All voices must speak for him Every child that is born must have a just claim for his bread"—EMERSON.

THE simple and admirably arranged system by which that service of justice—the protection of foundling children—is conducted in France is briefly as follows. There is a principal depôt in Paris with subsidiary depôts in the other principal towns of France into which the foundling children are first collected from all over the country. So severe in France is the punishment for ill-treating or exposing children, and so great is the facility to abandon them to the public care, that this preliminary collection presents but little difficulty. In the majority of cases mothers who wish to abandon their children bring them to the depôt themselves and voluntarily resign their parental rights. The service is open to all; none are denied the right to make use of it. In addition to the children thus voluntarily abandoned the State also demands the care of all children who are being physically ill-treated or morally corrupted by their parents. Received into the depôt the child is kept there for as short a time as possible. It is fed, clothed, and baptised, and every attention is given by medical treatment and nursing to correct physical ailment and to obtain a vigorous state of health. When these preliminaries are fulfilled the child is immediately removed to the country by an appointed *nourrice* (nurse) who forthwith incorporates the newcomer into her own family as one of its natural inmates. This placing of the children in the home of a *nourrice* is not undertaken without careful forethought. Each child is considered as an individual and particular attention is given to possible heredity in weighing the decision as to its future home. At the same time the welfare of the families about to receive the children is also taken into account. All weakly children and those who are known to be the offspring of vicious parents are specially placed and closely watched during development in order that other children may be protected from physical or moral infection and contamination. No woman is accepted as a *nourrice* unless she is either personally known to the authorities or can afford credentials of honesty, respectability, and capability for the office which she undertakes to fulfil. A register of women who are certified as fit to become nurses is kept at the principal depôts. The supply is in excess of the demand; consequently, as occasion arises, a selection amongst them is possible to meet the special requirements of the children. Each nurse, when a child is handed over to her care, receives definite instructions as to the duties and obligations for the fulfilment of which she is to be held responsible. She has to take the child into her home, to suckle it for the proper term, to clothe and to feed it, and at the proper age to supervise its attendance at school; in short, she is in every way to act as a natural mother should to her own child.

In the way described above, then, each child abandoned in France may find a new home, a natural home, and may grow up under normal conditions. The nurse becomes its mother, her husband its father, and her children its brothers and sisters. Not only physical wants, but the imperative demands of childhood for love, tenderness, and companionship are thus satisfied The child remains in the family till the age of 14 years Apart from home training it has received the free education of the schools which the law allows for all children. After this age the child is apprenticed to some trade, craft, or business, and is not finally released from the public surveillance and protection until it has been made good for something and can begin life with an "open field and fair play."

This is the machine as it exists in principle. The machine at work has possibly other aspects. Many defects may then appear that require constant reparation and attention. A multitude of weaknesses is inseparable from all machinery. The corruption of moth and dust, the possibility of abuses arising from rival interests can never be eliminated. The machine here described is the machine as an ideal—the machine of glorified record from blue-book and hearsay; and when all has been said of human institutions the ideal is the only final criterion. With our institutions, at any rate, it is better to fall beneath a high ideal than to approximate a low one. This at least can be said of the French system for assistance to helpless children—that the ideal is the right one, however it works out in practice; that the effort to administer the highest justice is noble and good, whatever infirmity the results may possess. To estimate these results personally would be a long and difficult task, involving an intimacy with families all over France and the surveillance of children through many years. This is impossible, and we must therefore rest content with the reports of the inspectors—reports based on personal observation, optimistic, telling of practical issue in adequate proportion to the lofty theoretical aim. And that such reports are not widely exaggerated (if exaggerated at all), that the mechanism seems practicably workable and full of vitality, can be deduced from a limited personal observation possible to everyone—by "a seeing with the eyes and touching with the hand" the very heart of the whole mechanism as it throbs and works every day at the headquarters of the institution in Paris.

A visit to the hospice of the *enfants trouvés* leads the imagination to think of the emotions that must have been witnessed at its threshold. Standing in the Boulevard Rochereau, a quiet road on the outskirts of the Quartier Latin, where the never-ceasing roar of a great city reaches only as a distant murmur, this unobtrusive stone building has taken part in every variety of anguish which maternity can produce in woman. What a motley show would be the long procession of mothers who have passed over this threshold—mothers from all classes and of every type of womanhood, possessed by every degree of maternal conflict from all but indifference to heart-broken despair; vagabonds, prostitutes, criminals, young and old, virtuous and depraved—all with the same intent, to give up to the public care their rights to the precious burden each carries in her arms

This quiet unobtrusive building in the Boulevard Rochereau is the town house of the family of foundling children whose country residences are scattered over France The main structure, and many smaller buildings behind it, stretch over a wide area. Gardens surround the buildings; their trees appearing above a long, high wall attract the passer-by to inquire what is this snug and peaceful refuge so securely inclosed. Despite the formidable wall and a massive door admission is readily obtained by the stranger. Here, as at all hospitals or public institutions in Paris, the stranger is welcomed; his curiosity is understood and never maliciously interpreted and every obliging effort is made to give it honest satisfaction. There is cordiality even in the *concierge* who refers you to the manager; in the manager who is delighted to see you and summons a guide; in the guide who forthwith takes you in hand and leads the way. You feel at ease and you know you are to see the machine at its normal daily work, at no exceptional performance specially prepared for visitors or patrons.

Once inside you are struck by the bustle of business about you—a business suggestive of play rather than work—hardness, weariness, and care are all absent from the scene. There are women in uniform rushing to and fro, groups of women excitedly talking, their faces serious and preoccupied and every one of them good-humoured and light-footed A gigantic nursery the place seems to be with children and babies everywhere. You come across them at each turning; on every landing women are seen in every direction with human bundles in their arms. The children cling to you, they roll on the floor under your feet, files of them in pretty uniform march by in procession A number of babies are set out on shelves like bales of merchandise, sorted and ticketed. Through this maze of children you pick your way, preceded by your guide A marvellous creature is this guide, overflowing with energy, with a fine stride and a voluble tongue. With the air and voice of a proprietor she unfolds the mystery of the business and displays her living ware. There is a certain condescension in her voice as she replies to your questioning—a certain pity for the merely masculine and its inevitable ignorance of baby ware. Her explanations are as eloquent and as detailed as a mother's of her offspring. She tells you that this building is not only the town house of the *enfants trouvés*, that it has a second and still more important function. Its chief function is to serve as a temporary refuge and *crèche* for children whose parents, on account of some misfortune, are unable temporarily to provide for them. Thus babies prematurely born and the babies of women who are sick are sent here to be provisionally suckled, and the children of parents who are out of employment, or who have been temporarily three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 357, 375, and 486 in the three preceding weeks, further rose last week to 681, and were 213 above the corrected average. The causes of 89, or 1·4 per cent., of the deaths in the 76 large towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Hull, Newcastle, and in 35 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Aston Manor, Liverpool, St. Helens, Rotherham, Middlesbrough, Sunderland, and Gateshead.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3, 21·8, and 23·9 per 1000 in the three preceding weeks, declined again to 23·6 per 1000 during the week ending Feb. 15th, but was 1·0 per 1000 above the mean rate during the same period in the 76 large English towns. Among these Scotch towns the death-rates ranged from 12·5 in Perth and 19·5 in Aberdeen to 25·1 in Leith and 25·2 in Glasgow. The 761 deaths in these towns included 20 which were referred to whooping-cough, 16 to diarrhœa, 12 to measles, 10 to "fever," three to scarlet fever, three to diphtheria, and two to small-pox. In all 66 deaths resulted from these principal zymotic diseases last week, against 66 and 83 in the two preceding weeks. These 66 deaths were equal to an annual rate of 2 0 per 1000, which was 0·2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 19 and 17 in the two preceding weeks, rose again last week to 20, of which 10 occurred in Glasgow, three in Paisley, and three in Leith. The deaths from diarrhœa, which had been 20, eight, and 23 in the three preceding weeks, declined again to 16 last week, and included six in Dundee, five in Glasgow, and two in Edinburgh. The fatal cases of measles, which had been 31, 23, and 19 in the three preceding weeks, further decreased last week to 12, of which eight were registered in Glasgow and two in Dundee. The deaths referred to different forms of "fever," which had been three and five in the two preceding weeks, further rose to 10 last week, and included five in Glasgow, three in Edinburgh, and two in Greenock. The fatal cases of scarlet fever, which had been four, seven and 10 in the three preceding weeks, declined again last week to three, of which two were registered in Greenock. The deaths from diphtheria, which had been five and eight in the two preceding weeks, decreased to three last week, and included two in Glasgow, where the two fatal cases of small-pox were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 128, 141, and 173 in the three preceding weeks, further rose last week to 211, and were 58 in excess of the number in the corresponding period of last year. The causes of 26, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·9, 22·7, and 23 8 per 1000 in the three preceding weeks, rose again to 25 7 per 1000 during the week ending Feb. 15th. During the past four weeks the death-rate has averaged 23·3 per 1000, the rates during the same period being 21·3 in London and 21·4 in Edinburgh. The 187 deaths of persons belonging to Dublin registered during the week under notice showed an excess of 14 over the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against eight, four, and five in the three preceding weeks; of these [illegible] three resulted from measles, three from whooping-cough, [illegible] two from "fever," two from diarrhœa, and one from scarlet fever. These 11 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rates during the same period being 2·4 in London and 1·1 in Edinburgh. The deaths from whooping-cough, which had been one and two in the two preceding weeks, further rose last week to three. The 187 deaths in Dublin last week included 22 of children under one year of age and 60 of persons aged upwards of 60 years; the deaths of infants showed a slight decline from the number in the preceding week, while those of elderly persons were considerably in excess. Five inquest cases and seven deaths from violence were registered; and 71, or nearly two-fifths, of the deaths occurred in public institutions. The causes of 12, or more than 6 per cent., of the deaths in Dublin last week were not certified.

### VITAL STATISTICS OF LONDON DURING JANUARY, 1902.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of *the nine diseases specified in the table* was equal to an annual rate of 11·4 per 1000 of the population, estimated at 4,579,107 in the middle of this year. In the three preceding months the rates had been 13 8, 11·6, and 10 6 per 1000 respectively. The rates were considerably below the average in Kensington, Chelsea, Hampstead, Wandsworth, and Woolwich, while they showed the largest excess in St. Pancras, Holborn, Bethnal Green, Stepney, Poplar, and Deptford. During the five weeks ending Feb. 1st, 1385 cases of small-pox were notified, showing a further considerable increase over the numbers in recent months; the greatest proportional prevalence of this disease was in the City of Westminster, St. Pancras, Holborn, Shoreditch, and Stepney. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 284, 427, and 666 at the end of the three preceding months, had further risen to 1135 at the end of January; the weekly admissions averaged 297, against 72, 110, and 173 in the three preceding months. The prevalence of scarlet fever during January showed a marked decline from that recorded in any recent month; among the various metropolitan boroughs this disease was proportionally most prevalent in Stoke Newington, Poplar, Battersea. Camberwell, and Deptford. The Metropolitan Asylums hospitals contained 2501 scarlet fever patients at the end of the month, against 3281, 3186, and 3080 at the end of the three preceding months; the weekly admissions averaged 266, against 392, 352, and 297 in the three preceding months. Diphtheria was slightly less prevalent during last month than in any of the three preceding months; the greatest proportional prevalence of this disease occurred in Fulham, St. Pancras, Islington, Hackney, Bethnal Green, and Lewisham. There were 1231 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1570, 1504, and 1369 at the end of the three preceding months; the weekly admissions averaged 167, against 243, 200, and 160 in the three preceding months. The prevalence of enteric fever showed a considerable decline from that recorded in the preceding month; among the various metropolitan boroughs this disease was most prevalent in the City of Westminster, Islington, Holborn, Shoreditch, Stepney, Poplar, and Bermondsey. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 291, 245, and 195 at the end of the three preceding months, had further declined to 128 at the end of January; the weekly admissions averaged 18, against 38, 32, and 21 in the three preceding months. Erysipelas was proportionally most prevalent in Hammersmith, Hackney, Shoreditch, Southwark, and Deptford. The 42 fatal cases of puerperal fever included five in Lambeth, five in Hackney, four in St. Marylebone, four in Wandsworth, three in Stepney, and three in Lewisham.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ending Feb. 1st the deaths of 8021 persons belonging to London were registered, equal to an annual rate of 18·3 per 1000, against 15·4, 20·0, and 18·8 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 12·0 in Hampstead, 13·6 in Wandsworth, 15·1 in Battersea, 15·2 in Lewisham, 15·4 in Kensington, and 15·5 in Stoke Newington; the highest rates were 21·2 in Shoreditch, 21·3 in Bermondsey, 22 4 in Bethnal Green, 22·8 in the City of London, 23·9 in Holborn, and 24 0 in Finsbury. The 8021 deaths from all causes included 839 which were referred to the principal zymotic diseases; of these 201 resulted from small-pox, 234 from measles, 67 from scarlet fever, 132 from diphtheria, 111 from whooping-cough, 36 from enteric fever, and 58 from diarrhœa. The lowest death-rates from these on the part of any midwife practising within their area, and should a *primâ facie* case be established to report the same to the Central Midwives Board.

(3) To suspend any midwife from practice in accordance with the rules under this Act, if such suspension appears necessary.

(4) To report at once to the said Board the name of any midwife practising in their area convicted of an offence.

(5) During the month of January of each year to supply the secretary of the Central Midwives Board with the names and addresses of all midwives who have notified their intention to practise within their area and to keep a current copy of the roll of midwives accessible at all reasonable times for public inspection.

(6) To report at once to the Central Midwives Board the death of any midwife or any change in the name or address of any midwife in their area so that the necessary alteration may be made in the roll.

(7) To give due notice of the effect of the Act to persons at present using the title of midwife.

The local supervising authority may delegate, with or without any restrictions or conditions as they may think fit, any powers or duties conferred or imposed upon them by or in pursuance of this Act to a committee appointed by them and consisting either wholly or partly of members of the council and the provisions of subsections one and two of Section 82 of the Local Government Act, 1888, shall apply to every committee appointed under this section and to every council appointing the same, and women shall be eligible to serve on any such committees.

9. *Delegation of powers to district councils.*—A county council may delegate with or without any restrictions or conditions as they may think fit any powers or duties conferred or imposed upon them by or in pursuance of this Act, to any district council within the area of the county, and the powers and duties so delegated may be exercised by a committee appointed by such district council, and consisting either wholly or partly of members of the district council and women shall be eligible to serve on any such committee. Any expenses incurred by a district council in the execution of any powers or duties so delegated shall to an amount not exceeding such sum as may be prescribed by the county council be repaid to such district council as a debt by the county council and any excess above the sum so prescribed shall be borne by the district council as part of their ordinary expenses.

The provisions of this section shall apply to the administrative county of London in like manner as if each metropolitan borough were a county district and the borough council were the district council of that district.

10. *Notification of practice.*—Every woman certified under this Act shall, before holding herself out as a practising midwife or commencing to practise as a midwife in any area, give notice in writing of her intention so to do to the local supervising authority, or to the body to whom for the time being the powers and duties of the local supervising authority shall have been delegated under this Act.

Such notice shall be given to the local supervising authority of the area within which such woman usually resides or carries on her practice and the like notice shall be given to every other local supervising authority or delegated body within whose area such woman at any time practises or acts as a midwife within 48 hours at the latest after she commences so to practise or act.

Every such notice shall contain such particulars as may be required by the rules under this Act to secure the identification of the person giving it, and if any woman omits to give the said notices or any of them, or knowingly or wilfully makes or causes or procures any other person to make any false statement in any such notice she shall be guilty of a misdemeanour and shall on conviction thereof be liable to a fine not exceeding £5.

11. *Penalty for obtaining a certificate by false representation.*—Any woman who procures or attempts to procure a certificate under this Act by making or producing or causing to be made or produced any false and fraudulent declaration, certificate, or representation, either in writing or otherwise shall be guilty of a misdemeanour and shall on conviction thereof be liable to be imprisoned, with or without hard labour, for any term not exceeding 12 months.

12. *Penalty for wilful falsification of the roll.*—Any person wilfully making or causing to be made any falsification in any matter relating to the roll of midwives shall be guilty of a misdemeanour, and shall be liable to be imprisoned with or without hard labour for any term not exceeding 12 months.

13. *Prosecution of offences.*—Any offences under this Act punishable on summary conviction may be prosecuted by the local supervising authority.

The expenses of any such prosecution shall be defrayed by the council of the county or county borough in which the prosecution takes place.

14. *Appeal.*—Where any woman deems herself aggrieved by any determination of any court of summary jurisdiction under this Act, such woman may appeal therefrom to the court of quarter sessions.

15. *Expenses of local supervising authority.*—Any expenses under this Act payable by the council of a county or county borough shall be defrayed out of the county fund or out of the borough fund or borough rate, as the case may be.

16. *Act not to apply to medical practitioners.*—Nothing in this Act respecting midwives shall apply to legally qualified medical practitioners.

17. *Extent of Act and action by English Branch Council.*—This Act shall not extend to Scotland or Ireland.

The General Medical Council shall act by the English Branch Council, which for all purposes of this Act shall occupy the place of the General Medical Council.

18. *Definitions.*—In this Act—

The term "midwife" means a woman who is certified under this Act.

"Central Midwives Board" means the Board constituted under this Act for the purpose of carrying out the provisions of this Act.

# ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary meeting of the Comitia was held on Tuesday, Feb. 18th, Sir WILLIAM SELBY CHURCH, the President, being in the chair.

A gracious reply was received from His Majesty the King, thanking the President and Fellows of the College for the resolution adopted at the last meeting and for the loyal words in which they alluded to His Majesty.

The PRESIDENT announced that in consequence of the Coronation the Croonian Lectures would be given a week earlier than was announced in the calendar (the revised dates are June 10th, 12th, 24th, and 26th). The President also announced that an intimation had been received from the Privy Council to the effect that the Egyptian Medical Congress would be held from Sept. 19th–23rd.

The following communications were received: (1) From the Secretary of the College of Surgeons reporting certain proceedings of their Council on Feb. 13th; (2) from the Sanitary Institute, inviting the College to send delegates to the annual congress to be held at Manchester on Sept. 9th (the President nominated Dr. G. V. Poore and Dr. W. H. Corfield); and (3) from the Clerk to the Management Committee of the Chelsea Physic Garden, inviting the College to appoint a member of the committee for a term of four years (the President nominated Dr. W. Cayley).

The PRESIDENT then dissolved the Comitia.

# VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8456 births and 6451 deaths were registered during the week ending Feb. 15th. The annual rate of mortality in these towns, which had been 17·7, 17·9, and 20·6 per 1000 in the three preceding weeks, further rose last week to 22·6 per 1000. In London the death-rate was 25·9 per 1000, while it averaged 21·2 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 11·7 in Hornsey, 12·2 in Handsworth, 12·5 in East Ham, 13·4 in Barrow-in-Furness, 13·9 in Walthamstow, and 14·1 in Portsmouth and in Reading; the highest rates were 26·7 in Norwich, 26·8 in Liverpool, 27·3 in South Shields, 27·5 in Preston, 29·7 in St. Helens, 29·9 in Rhondda, 31·0 in Merthyr Tydfil, and 31·3 in Burnley. The 6451 deaths in these towns last week included 525 which were referred to the principal zymotic diseases, against 444 and 584 in the two preceding weeks; of these 525 deaths 134 resulted from whooping-cough, 124 from measles, 76 from diphtheria, 60 from small-pox, 52 from scarlet fever, 46 from "fever" (principally enteric), and 33 from diarrhœa. No death from any of these diseases occurred last week in Hastings, Portsmouth, Ipswich, Devonport, Handsworth, Smethwick, Bury, Rochdale, or Barrow-in-Furness; while the highest zymotic death-rates were recorded in Tottenham, Hanley, Birmingham, Leicester, St. Helens, Burnley, Stockton-on-Tees, and South Shields. The greatest proportional mortality from measles occurred in Croydon, Southampton, St. Helens, Warrington, Burnley, Blackburn, Huddersfield, Sheffield, and York; from diphtheria in Hanley and St. Helens; from whooping-cough in Leyton, Birmingham, Aston Manor, Liverpool, Leeds, Stockton-on-Tees, South Shields, and Rhondda; and from "fever" in Sunderland. The mortality from scarlet fever showed no marked excess in any of the large towns. Of the 60 fatal cases of small-pox last week 54 belonged to London, three to Tottenham, and one each to West Ham, East Ham, and Plymouth. There were 1185 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, Feb. 15th, against 870, 1135, and 1102 at the end of the three preceding weeks; 390 new cases were admitted during the week, against 204, 499, and 287 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had decreased from 3137 to 2500 on the seven preceding Saturdays, further declined to 2455 at the end of last week; 260 new cases were admitted during the week, against 299, 226, and 277 in the three preceding weeks. *Influenza was certified as the primary cause* of 51 deaths in London last week, against 18, 26, and 40 in the diseases were recorded in Chelsea, Hampstead, Wandsworth, Deptford, Greenwich, and Lewisham; and the highest rates in Fulham, St. Pancras, Islington, Holborn, Finsbury, and Stepney. The 201 fatal cases of small-pox considerably exceeded the numbers in recent months; the greatest proportional mortality from this disease occurred in the City of Westminster, St. Pancras, Holborn, Finsbury, and Stepney. The 234 deaths from measles showed a slight decrease from the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, Kensington, Hammersmith, Fulham, and Islington. The 67 fatal cases of scarlet fever showed a marked decline from the corrected average number; the greatest proportional fatality from this disease occurred in Fulham, St. Pancras, Southwark, and Bermondsey. The 132 deaths from diphtheria were 87 below the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, St Pancras, Islington, Hackney, Finsbury, and Bethnal Green The 111 fatal cases of whooping-cough were equal to only about one-third of the corrected average number; this disease showed the highest proportional fatality in Shoreditch, Bethnal Green, Stepney, Poplar, and Lewisham. The 36 deaths referred to enteric fever were 30 below the average in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs the "fever" death-rate was highest in St. Marylebone and St. Pancras. The 58 fatal cases of diarrhœa showed a considerable decline from the corrected average number; the greatest proportional fatality from this disease occurred in Hammersmith, Chelsea, the City of Westminster, Finsbury, Shoreditch, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from these diseases was nearly 15·6 per cent. below the average.

Infant mortality in London during January, measured by the proportion of deaths among children under one year of age to registered births, was equal to 121 per 1000. The lowest rates of infant mortality were recorded in Fulham, St. Marylebone, Hampstead, Camberwell, Deptford, and Lewisham; and the highest rates in Paddington, Stoke Newington, the City of London, Shoreditch, Poplar, and Southwark.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: E. H. Meaden to the *Bulwark* and A. J. Pickthorn to the *Ganges*. Surgeons: J. A. L. Campbell to the *Bulwark*; R. A. Kirby to the *Vernon*; A. Gaskell to Chatham Hospital, and C. R. Rickard to the *Boscawen*.

### ROYAL ARMY MEDICAL CORPS.

*1st Life Guards:* Major Nicholas C. Ferguson, C.M.G., from Royal Army Medical Corps, to be Surgeon-Major. Dated Feb. 15th, 1902

Lieutenant-Colonel John McLaughlin retires on retired pay on account of ill-health. Dated Feb 19th, 1902.

The undermentioned Majors to be Lieutenant-Colonels (dated Feb. 4th, 1902):—William Dick, Francis John Jencken, Francis Harper Treherne, Samuel Foster Lougheed, C.M.G., John Courtenay Haslett, Herbert James Barratt, Herbert Ellison Rhodes James, Henry Octavius Trevor, Alexander Fraser Russell, C.M.G., Robert James Leech Fayle, D.S O., John William Jerome, William Watson Pike, D.S.O., Lewis Haywood, James Murray Irwin, Ernest Octavius Wright, Francis Henry Merceron Burton, Charles Edward Nichol, and William Albert Morris.

Surgeon-Captain J. H. Stacey, Army Medical Reserve, assumes the duties of assistant to the medical officer in charge at Norwich. Lieutenant W. J. S. Harvey has been posted to the depôt at Aldershot for duty. Surgeon-Lieutenant Davies has left Aldershot for South Africa for duty with mounted infantry.

### IMPERIAL YEOMANRY.

Dorset (Queen's Own) Surgeon-Captain W. Rendall resigns his commission, and is granted the rank of Surgeon-Major, with permission to wear the uniform of the regiment, on retirement. Surgeon-Lieutenant Lloyd John Hollis Oldmeadow, from 2nd Volunteer Battalion the Royal Fusiliers, to be Surgeon-Lieutenant. Charters James Symonds to be Surgeon-Lieutenant.

### VOLUNTEER CORPS.

*Royal Garrison Artillery (Volunteers):* 1st Ayrshire and Galloway: Surgeon-Major J. Thomson to be Surgeon-Lieutenant-Colonel. 1st Worcestershire: Surgeon-Lieutenant A. C Oldham to be Surgeon-Captain. *Rifle:* 1st Dumbartonshire: Surgeon-Lieutenant J. R. Foulds resigns his commission. 1st Volunteer Battalion the Buffs (East Kent Regiment): Surgeon-Lieutenant L. A. E. Larking to be Surgeon-Captain. 2nd Cadet Battalion the King's (Liverpool Regiment): the appointment of Henry James Bailey as Surgeon-Lieutenant, announced in the *London Gazette* of Jan. 17th, 1902, is cancelled at his own request.

### SOUTH AFRICAN WAR NOTES.

Lieutenant M. F. Foulds, R.A.M.C. (invalided), Lieutenant-Colonel S. Townsend, R.A.M.C., Civil Surgeon W. B. Bannerman, Civil Surgeon R. Brown, Civil Surgeon A. J. Knowlton, Civil Surgeon Ganvie (invalided), and Civil Surgeon I. Blore (invalided), are returning to England in the *Avoca* which left Port Natal on Feb. 7th.

Civil SurgeonPenn is reported to be improving (Feb. 13th).

### A FRENCH SURGEON'S VISIT TO THE EXPEDITIONARY FORCE HOSPITALS AT PEKING.

In the course of what he modestly styles "une simple promenade" through the several hospital establishments of the international expeditionary force at Peking in January, 1901, Dr. Machenaud, principal medical officer of the French military hospital in the Chinese capital, took note of many interesting details, and has recorded his impressions in a paper which appears in the *Archives de Médecine Navale* for last December. The first hospital visited was that belonging to the American troops who were cantoned in the Palace of Agriculture, opposite the Palace of Heaven, which was occupied by the British, the terminus of the Peking and Tientsin railway separating the two cantonments. The American hospital was accommodated suitably enough in one of the pavilions of the palace, and contained 100 beds, the staff consisting of Chief Surgeon-Major Yves and two assistants. On the day Dr. Machenaud paid his visit there were 43 patients, and among them he was told that there was not a single case of typhoid fever. The establishment and everything connected with it seem to have met with the visitor's unqualified admiration, the installation and equipment being as near perfection as possible. In the first place Dr. Machenaud was shown the dispensary, and the drugs, which were all compressed, were found to be in perfect condition; chloral and salol alone, amongst a complete assortment of medicines, being found liable to deterioration after the opening of their flacons. In a little case, the same size as the volume containing the Regulations for his service, Dr. Machenaud saw the pharmaceutical and surgical supply of a battalion for three months. In addition to thermometer, hypodermic syringe, "and all the usual instruments," there were about 40 little flasks full of compressed tablets, besides "pastilles" for subcutaneous injection. Nothing could be more portable. The case might be carried in the pocket of the medical officer who could not but feel satisfaction at having an adequate armament available at the shortest notice. Compressed tampons, sterilised silk and catgut, an apparatus for distilling and aerating water on a large scale, a portable kitchener, portable table equipment, a petroleum stove for keeping foods and drinks warm, folding chairs, besides several other things which struck the visitor as exceptionally meritorious, are described at considerable length but can only be alluded to here. Dr. Machenaud was also favourably impressed by a hypodermic syringe which certainly seems well adapted for the rough usage of military service. It consists of two metal cylinders, one hollow and the other solid. The latter fits the former accurately and is graduated to show the amount of fluid injected. There is no glass to break or piston to get out of order, and perfect disinfection can be assured by plunging into boiling water. The British "ambulance," which was the objective of Dr. Machenaud's second visit, had the advantage of being splendidly housed, but the visitor has little to say that is complimentary. It is true that he deals chiefly in generalities, but evidently our hospital at Peking was far from perfect in his estimation. The material sent from India appeared to him to be incongruous (*disparate*) and to be

## ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JANUARY, 1902.

* Including membranous croup.

is probable that the prognosis in this variety of valvular disease depends as much upon the condition of the heart-wall as upon the size of the mitral orifice. If the cardiac muscle remains healthy it is possible not only for life to be prolonged, but for the man or woman in whom the mitral orifice is narrowed to live an active life. For example, in an ostler, aged 64 years, who was busy at his work to within a few days of his death, which was caused by acute bronchitis, I found a mitral orifice which would only admit one finger.

I am, Sirs, yours faithfully,

THEODORE FISHER.

Feb. 18th, 1902.

*To the Editors of* THE LANCET.

SIRS,—The "preliminary note" suggesting the probable advisability of treating certain hopeless cases of mitral stenosis by dividing the constriction, which Sir Lauder Brunton published in THE LANCET of Feb 8th, p. 352, merits, I think, serious consideration at the hands of experienced surgeons. In THE LANCET of April 2nd, 1898 (p. 927), I concluded a communication on Cardiac Peristalsis with these words, "I anticipate that with the progress of cardiac surgery some of the severest cases of mitral stenosis will be relieved by slightly notching the mitral orifice, and trusting to the auricle to continue its defence." Believing, as I there maintained, that the auricle, in cases of mitral stenosis has an important rôle in preventing regurgitation at the mitral, it seems to me probable that slightly notching the valve, though increasing the incompetence at the orifice, would not result in a greurgitation comparable in evil to the advantages gained by facilitating the onflow. It is, however, very important that the orifice should not be cut too freely. Sufficient stenosis should remain to render a prolonged contraction of the auricle necessary to fill adequately the ventricle, so that the auricular contraction may continue into ventricular-systolic time and help to prevent regurgitation at the mitral orifice. The question which Sir Lauder Brunton raises whether to elongate the natural opening or cut the valves transversely is a problem somewhat similar to "which foot should be drawn down in podalic version?" Probably in practice they may be congratulated who succeed with either.—I am, Sirs, yours faithfully,

Mentone, Feb. 12th, 1902. D. W. SAMWAYS.

## UREA IN THE TREATMENT OF TUBERCULOSIS.

*To the Editors of* THE LANCET.

SIRS,—The communications from Dr. H. Harper in THE LANCET of March 9th (p. 694), June 15th (p. 1672), and Dec. 7th (p. 1567), 1901, detailing his experience in the use of urea in tuberculosis have greatly interested me, especially as this same treatment was suggested, and to a certain extent employed, by Dr. Samuel G. Dixon of this city several years ago. Like Dr. Harper, Dr. Dixon appreciated the fact that certain animals and persons that had not had tuberculosis and that were not inoculated against it possessed a positive immunity to this disease and in seeking the reason for this independently observed that gout and tuberculosis do not often occur simultaneously in the same subject. That this latter fact had already been noted by Sir Dyce Duckworth, and perhaps by others, seems to have escaped the attention of both investigators at the time they were respectively convinced of the antagonism between the tuberculous and the gouty or rheumatic diathesis, though it must be remembered that Dr. Dixon referred to the first results of his experiments based on the theory of this antagonism very soon after the publication of Sir Dyce Duckworth's "Treatise on Gout," from which Dr. Harper quotes, and that in these experiments he used in turn each member of the group—creatin, urea, uric acid, taurin, &c.[1] Later, and because of its close resemblance to urea in formula, he used a vegetable derivative, thiosinamin, in combination and alternation with the above-mentioned nitrogenous metabolic products. It may be interesting to Dr. Harper and other readers of THE LANCET to know that Dr. Dixon always administered these substances subcutaneously and in comparatively small doses. Whether the larger amounts which seem to have been necessary when the urea was given by the mouth to Dr. Harper's patients were partially wasted in the economy because of the action of the digestive juices or of changes during absorption is a question for future investigation.

In addition to his successful experiments upon animals most favourable results were secured in several cases of long-continued and intractable disease, such as psoriasis, acne pustulosa, and lupus.[2] Unfortunately, the only cases of pulmonary tuberculosis in which he ventured to administer the nitrogenous substances were far advanced and of mixed infection, consequently negative rather than positive results were noted. This serves to confirm Dr. Harper's opinion concerning the administration of urea in such cases. Just at this time the election of Dr. Dixon to the presidency of the Academy of Natural Sciences of Philadelphia and other important offices and his consequent duties compelled him to postpone his experimental studies and up to the present time no leisure or opportunity for resuming them has come to him.

The above statements and the references noted will, I trust, be sufficient to establish the priority of Dr. Dixon in this line of work, though I am sure that the following quotation from one of his papers[3] will convince your readers not only of his appreciation of the breadth and extent of the problems involved, but also that no one is more ready than he to congratulate Dr. Harper upon his apparent success and to encourage his future labour in this direction:—

> However, I think that sufficient has been said to open up the very broad question as to whether the conditions that predispose to or favour the development of tuberculosis are not those of faulty, deficient, or abnormal nitrogenous metabolism, and whether the truly scientific method of obtaining immunity against this dread malady will not necessarily come through a thorough understanding of the processes involved and the changes that take place in the various cells and tissues of the body in so far as they are related to the assimilation, secretion, and excretion of nitrogen and nitrogenous compounds. Believing that this is largely so I would, therefore, suggest that future work carried on along the following lines promises to return good results and to lead to substantial ground on which we may base our hopes of eventually securing positive immunity. Such work should include, I think—
>
> 1. A systematic investigation as to the amount of nitrogen secreted by the healthy, the tuberculous, and the lithæmic, and the relative proportions of the various nitrogenous products in each case.
> 2. A tabulation of the clinical results from the systematic *hypodermic* administration of tuberculin, nucleins, and members of the amide group of metabolic products to healthy, tuberculous, and lithæmic subjects, preferably the same, if possible, as those in the first series of experiments; the results to include full reports as to temperature, secretion and excretion of nitrogen and nitrogen compounds, increase or decrease in white blood corpuscles, condition of subject, &c. A considerable amount of this work has been done but far more is needed. Collateral experiments upon animals would also have their place here and would be of value.
> 3. Experimentation as to special treatment or diets as would be indicated by a study of the results of the above series of experiments.
>
> Confident that such a work as indicated will be rich in returns to those that undertake it, and trusting that others may be induced by these remarks to join with me in carrying it out, either in general or in detail, I am sure that in whatever way immunity against tuberculosis is eventually secured it will be in very truth a blessing to humanity almost inconceivable and which will be measured least of all by the undying fame of its discoverers.

I am, Sirs, yours faithfully,

SENECA EGBERT, M.D.,

Professor of Hygiene in the Medico-Chirurgical College of Philadelphia, U.S.A.

Philadelphia, Jan. 11th, 1902.

## THE DECEASED WIFE'S SISTER BILL.

*To the Editors of* THE LANCET.

SIRS,—I beg to urge the medical profession to show more interest in the Deceased Wife's Sister Bill. The influence of the profession is an acknowledged factor in public life, and I feel it to be a public duty to press for the removal of an awkward and useless clause in matrimonial law where, there being no blood relationship, conjugal union would be not only desirable but beneficial to the community, and to place the bar of prohibition against all blood-marriages—cousins within the third and fourth degree. I believe we should thus improve the status of the step mother and secure more satisfactory results from second marriages. Furthermore, by abolishing blood-marriages the constitution of many families would become amended.

I am, Sirs, your faithfully,

Stockport, Feb. 11th, 1902. J. GOOD.

composed of old trash (*vieilleries*). The ventilation of the wards was defective and the warming by means of stoves could not be commended. Dr. Machenaud also says that there was no operation room (*salle de chirurgie*), and adds that no one showed him a bath-room, or a kitchen, or any reserve of material In the Japanese hospital, with a strength of 3500 men, there were only 33 patients, mostly convalescents from typhoid fever and bronchitis. The equipment, surgical as well as medical, was very complete. all the instruments and appliances having been manufactured in Japan, although the drugs were imported from Hamburg. Hory's apparatus for detecting cheating in recruits by means of prismatic glasses and coloured letters was included in the ophthalmic armament, which in other respects was very well supplied. When leaving the hospital Dr. Machenaud and his companions were much interested in the care their Japanese *confrères* took to wipe their feet on wet mats at the doors of the building. These mats, it seemed, were impregnated with a germicide solution, and the object of the attrition was to free the feet from any noxious microbes that might have been picked up while walking the hospital. The fourth and last establishment on the list was the German Field Hospital, No. 2. Here, in the opinion of the French visitor, everything was comparatively good, although not equal to the perfection of the American ambulance.

### INDIAN MEDICAL SERVICE.

The following is a list of the candidates for His Majesty's Indian Medical Service who were successful at the competitive examination held in London on Feb 10th and following days 30 candidates have been passed, instead of 17 as previously announced.

### THE NEW DESIGNATION FOR THE VOLUNTEER MEDICAL STAFF CORPS.

A correspondent writes: "There are, according to the Army List (January), one artillery volunteer medical officer, one engineer volunteer medical officer, one yeomanry medical officer, and eight regimental volunteer medical officers serving with the Royal Army Medical Corps, as against two only of the Volunteer Medical Staff Corps. Surely if the services of the Volunteer Medical Staff Corps merits its new designation and change of titles the other medical officers have earned for themselves and their colleagues—if the change from a professional to a combatant title is a compliment—a right to omit, if only for the sake of uniformity, the prefix of 'surgeon' when describing their rank."

### MEMORIAL TO THE LATE SURGEON-GENERAL HARVEY, C B.

It has been decided to start a subscription list for a memorial to the late Surgeon-General Robert Harvey, C.B. Director-General, Indian Medical Service, but the exact form of the memorial will not be decided till the subscription list is complete In the meantime subscriptions should be sent to the Editor, *Indian Medical Gazette*, care of Messrs. Thacker, Spink, and Co., Calcutta, by whom they will be duly acknowledged.

---

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.—The annual meeting of the subscribers to this institution was held on Feb. 7th, under the presidency of Mr. J. C. Williams The medical report stated that 1349 in-patients had been admitted during 1901, an increase of 67 as compared with 1900 The out-patients numbered 2795, as against 2654 in the previous year. During the year 51 nurses and 282 patients were sent to the Pearn Convalescent Home. The average daily number of occupied beds in the hospital was 109. The financial statement showed that the total income amounted to £7453 and the total expenditure to £7706

## SURGICAL OPERATION FOR MITRAL STENOSIS.

*To the Editors of* THE LANCET.

SIRS,—I should feel very keenly the disapprobation of my suggestion which your leading article of Feb. 15th seems to express were it not that it seems to me that it has been written under a certain amount of misapprehension in regard both to my object and experiments. I fear my preliminary note to THE LANCET of Feb. 8th has not been sufficiently explicit, for I have no intention whatever of leaving to other workers to prove or disprove the value of the treatment I have suggested I have just obtained a renewal of my licence and certificates and hope ere long to put my idea to experimental proof on the living animal, but "art is long and time is fleeting," and in the meanwhile many patients are suffering and dying from mitral stenosis. I cannot hope from my own experiments alone to prove the advisability of an operation against which, as stated in your leader, so many *a priori* arguments can be brought, and therefore hope that others will take up the subject as well as myself. I am quite aware of the responsibility that rests upon me for my suggestion, but I must state that while my experiments on the valves were made only on dead animals my knowledge of the manipulation of the living heart and of the effect upon it of wounds and punctures is based upon very numerous experiments made at intervals during the last 35 years. Some of these at least have, as I believe, borne good fruit. I do not wish to claim any credit which does not belong to me, and if I am wrong I shall be glad to be corrected, but I believe that the use of strychnine as a cardiac stimulant which is now so common in this country, although still neglected abroad, dates from an experiment made by Dr Cash and myself on the injection of strychnine into the interior of the frog's heart.[1] This showed so clearly the stimulating effect of the drug upon the heart that I have lectured upon it in my course of pharmacology and therapeutics at St. Bartholomew's Hospital every year since, and I think it is from this hospital that the practice of using strychnine both as a cardiac and respiratory stimulant has spread, with the result, as I believe, of saving many lives. I am, Sirs, yours faithfully,

Stratford place, W., Feb. 15th, 1902. LAUDER BRUNTON.

*To the Editors of* THE LANCET.

SIRS,—Referring to the preliminary note on the possibility of treating mitral stenosis by surgical methods by Sir Lauder Brunton in THE LANCET of Feb. 8th, p. 352, it may interest your readers to know that this suggestion was made by me to my colleague, Dr Lauriston Shaw, some years ago. I then went into the matter fully, both as to the surgical measures to be adopted and the physical conditions of the valve which seemed most suitable for such interference, and was quite prepared to act as soon as Dr. Shaw succeeded in finding a case likely to derive benefit. It was entirely due to his perhaps wise caution that the operation has not yet been performed by me. The method by which I proposed to divide the contracted valve through the ventricle was practically identical with that described by Sir Lauder Brunton. Personally I believe that the operation is feasible and, under certain circumstances, justifiable.

I am, Sirs, yours faithfully,
W. ARBUTHNOT LANE.

Cavendish-square, W , Feb. 15th 1902.

*To the Editors of* THE LANCET.

SIRS,—In your leading article upon the suggestion by Sir Lauder Brunton that it may be possible to operate upon some cases of mitral stenosis you give several reasons why such an operation is likely to fail. It seems to me that another may be added. Marked fibrosis of the cardiac muscle is found after death in many cases of mitral stenosis and it the recommending of a medical man save by another medical man. On this point, Sirs, I know that I cannot expect to obtain the agreement of a medical journal—*ex officio* you are bound to be against me; but you have many lay as well as professional readers, and to them I would say: Can you honestly think that it is not for the public interest—not for the "greatest good of the greatest number"—that information should be obtainable by uninstructed persons as to who are leading specialists, or, in the ordinary phrase, the "best people to go to" in this or that medical emergency—I will not even say the *best*, but *good* people? To whom could such information do harm? And is it not the case that the single argument against it is the unworthy argument above commented on—the argument that such information might not be unprejudiced. That, Sirs, can be urged against every kind of information whatsoever which is given to the public. It appears to me that each of such cases must be judged on its merits. Where a writer of reputation states publicly, assuming full responsibility for the statement, that such and such a fact is the case in his own personal experience he has a right, not, possibly, to his hearers' credence in the validity of his judgment, but to their belief in his *bona fides*

---

[1] St. Bartholomew's Hospital Reports for 1881, vol. xvi.,

In all human probability I shall never write another word concerning the medical profession in the strain to which objection has been made; I trust, however, that you will allow me to put on record the above, I fear, rather lengthy expression of my views and the intention by which the passage in question was actuated.

I am, Sirs, yours faithfully,
HARRY QUILTER.
Manchester-square, W., 1902

### *To the Editors of* THE LANCET.

SIRS,—Will you be good enough to reprint in your columns the inclosed letter which I have received from the Editor of "What's What"? I am, Sirs, yours faithfully,
H. W. ALLINGHAM
Feb 14th, 1902

[INCLOSURE.]

*To Herbert William Allingham, Esq.*

DEAR SIR,—I am very sorry to learn that certain references to you by name in my work entitled "What's What" have caused you annoyance and that you consider them "calculated to damage you with the public and the medical profession' I sincerely regret their insertion and shall omit from any future edition any such references, and indeed all mention of your name whatsoever. I wish also to state that the references referred to were absolutely unauthorised by you or anyone on your behalf and that you were in no way whatever responsible for or a party to such reference I need hardly say that it was very far from my intention to cause you damage or vexation, and, as it appears that my words have unwittingly done so, I authorise you to make any use of this expression of regret which you may think fit.

Yours obediently,
HARRY QUILTER
Manchester-square, W., Feb. 12th, 1902.

### *To the Editors of* THE LANCET.

SIRS,—My attention having originally been drawn to a reference to me in "What's What" by a visitor dining in my own house, I of course at once took steps to obtain redress for the annoyance. I drew the attention of the Registrar of the Royal College of Physicians to the book in question with the statement that the reference to me had been inserted without my previous knowledge and consent and to my very great annoyance I further placed the matter in the hands of the Medical Defence Union to obtain either a withdrawal of the article, or, if that were not possible, an apology from the publishers and an undertaking that the objectionable article should not appear in any future issue of the book.

I have this morning received a letter from the solicitor to the Medical Defence Union stating that he had received from the publishers "what amounts practically to an undertaking that the paragraph shall not appear in any further edition," and also that he had after correspondence with Mr. Quilter received from him a letter giving "the same assurance that I gave to Mr. Watson Cheyne," and expressing his regret for the notice respecting myself.

With regard to the remarks which appeared in the *Medical Times and Hospital Gazette* of Feb 8th, in which the suggestion is made that the sympathy of their professional brethren can only be extended to those whose names were unwarrantably made use of after they have dissociated themselves 'from what the public at all events is certain to regard as professional advertisement," I may say that all the members of the medical profession whom I have met who have been aware of the publication in question have expressed their sympathy in advance and have not taken part in the unworthy insinuations of the editor of the *Medical Times and Hospital Gazette*.

I am, Sirs, yours faithfully,
R. PERCY SMITH.
Queen Anne-street, W., Feb. 19th, 1902.

### *To the Editors of* THE LANCET.

SIRS,—As one of the medical men referred to in the publication called "What's What," to which attention has been called by Mr. W. Watson Cheyne in THE LANCET of Feb. 15th, p. 475, I shall be obliged if you will afford me the opportunity of saying that as soon as the paragraph in question was brought to my notice I wrote to the editor (Jan. 2nd) asking him to withdraw my name from any subsequent edition or reprint. Mr. Quilter replied (Jan. 6th): "I am quite disposed to act in the manner most agreeable to you and shall therefore most probably delete the paragraphs in question." I am, Sirs, yours faithfully,
PERCY FLEMMING.
Wimpole-street, W., Feb. 15th, 1902.

### *To the Editors of* THE LANCET.

SIRS,—Mr. W. Watson Cheyne's letter in THE LANCET of Feb 15th, p. 475, demands some reply from me. I cannot congratulate Mr. Watson Cheyne upon the choice of language which he deems it dignified to employ. In my humble judgment he might with more effect have utilised argument rather than abuse He could, for example, instead of three verbose epistles, have stated the following salient facts.

"What's What" was published some two months ago. It professes to be a popular compendium of general information. It contains an appendix (B) headed "London Medical Men" This begins: "This paragram (*sic*) is medically speaking an unforgivable sin. For the strictest rules of etiquette forbid a doctor to advertise. ...... We do not suggest that the doctors named hereafter are superior to their fellows; we simply state that we have had experience of them as capable men in the various maladies alluded to." Then about two columns are devoted to recommending about a dozen physicians and surgeons, with their addresses, as "having a most wonderful ear for diagnosis"; as "second to none for general disease of a grave character"; as "a first-rate man"; as "most fashionable"; as "kind and genial"; as having "an enormous reputation"; and as being "a long bony Scotchman with a grey moustache and beard"; while "Mr —— and Mr. Watson Cheyne are both undoubtedly first-class surgeons, and especially known in abdominal surgery," and so on.

In the first place, then, Mr. Watson Cheyne's attempt to excuse his friend on the ground that he acted in "ignorance" is clearly baseless, except that his friend is evidently ignorant of the Addisonian meaning of a "paragram." Some weeks ago the medical press condemned this appendix. For weeks medical men have been writing to the *Medical Times*, and doubtless also to you, Sirs, on the subject of this blatant advertisement. As it became evident that the gentlemen named were unaware of the invidious position in which they had been placed the *Medical Times* called their attention to the matter. Far from implying that they had any "knowledge of, or complicity in, the publication"—an extraordinary misstatement on the part of Mr. Cheyne—we said that it was "of course to be expected that the persons puffed in this unsavoury manner are altogether innocent of any participation in it" Confident of that fact, we also spoke of 'the gross liberty that has been taken in thus, without their knowledge or sanction, recommending them and their addresses in this pitiably patronising production."

I believe that the other gentlemen referred to are grateful that their attention has been called to the matter. One of them has just sent me a printed and ample apology which he at once obtained from the editor of "What's What"—a dignified vindication which may be commended to Mr. Watson Cheyne who, while condoning his friend's "ignorance," considers it offensive and evidence of a "jealous and dirty mind" that his attention has been directed to the matter; and this in the face of his admission to his friend that the "paragram" may cause him "irreparable damage" Verily Mr Watson Cheyne has a humorous method of expressing his gratitude to those who have saved him from his friend.

I refrain from further comment, but there is a great principle underlying this particular case—that there cannot be one law of right or wrong for Cavendish-square

## ACUTE SUFFOCATIVE PULMONARY ŒDEMA.

*To the Editors of* THE LANCET.

SIRS,—Under the title of "Acute Suffocative Pulmonary Œdema" some cases have been described by Dr. J. L Steven and Mr. T. Lissaman in THE LANCET of Jan. 11th (p. 73) and Feb. 8th (p 366) respectively. Dr. Steven states that with the exception of Dieulafoy he is unable to find in medical literature any adequate or satisfactory description of the condition. Mr. Lissaman states that he could find no description in any of the works at his disposal. The purport of this note is to point out that the characteristic symptoms have been very clearly described by Laennec. I cannot do better than give the quotation in full:—

"*Acute Suffocative Catarrh of Adults and Children.*—This variety does not appear to me to have hitherto sufficiently engaged the attention of physicians. It is very rare in adults. In young children it is more common and is often in them confounded with croup. It is recognised by the tracheal rhonchus perceptible by the naked ear, and by the imminent suffocation and frequent lividity of the face. The stethoscope detects, over the whole chest, a loud mucous (and very liquid) rhonchus, and a very frequent and usually irregular action of the heart. The disease is an acute catarrh affecting the whole, or a very large portion, of the mucous membrane of the lungs. Its duration is from 24 to 48 hours, or at most some days. At the end of this time either the patient dies or expectoration commences and puts an end to the suffocation, and the disorder then follows the progress of a simple acute catarrh. When the suffocation lasts there is but little cough, and the expectoration, if any, is altogether pituitous or fluid: it retains this character for some days at least, and then becomes more abundant; but recovery sometimes takes place without its ever becoming properly mucous, in which case the disease is only a variety of the acute bronchial phlegmorrhagy or pituitous catarrh. When, on the other hand, the expectoration becomes mucous, the disease is simply an ordinary acute catarrh, in which the suffocative character of the invasion is caused by the extent of tumefaction of the bronchial membrane and *by the great quantity of fluid secreted at once.*"

In this description we note more especially the extreme rarity of the condition in adults, the imminent suffocation and lividity, the very frequent pulse, the short duration of the symptoms, and the expectoration of a fluid secretion with but little cough. These are the points on which the writers of the articles have laid stress.

I am, Sirs, yours faithfully,
A. G. AULD.
Henrietta-street, W., Feb 11th, 1902.

## THE DANGERS OF A COMMON COLD.

*To the Editors of* THE LANCET.

SIRS,—The letter on "The Dangers of a Common Cold" by Dr. R P. White, in THE LANCET of Feb. 8th, p. 402, sets forth the common experience of the profession with regard to its rapid spread whatever its real nature may be. But how can we explain the fact that some are so susceptible while others never suffer? Since I began to study diet I have been astonished at the number of cases of which I have heard, even of medical men, who, by eating less and not so often, have found that their susceptibility to colds has quite gone Such facts as I have met with point to the conclusion that it is the system overcharged with the products of food which was not required and can act only as a poison to every organ in the body, which is most susceptible to colds. If such be a correct conclusion it may help us to understand susceptibility as well as immunity, and it is a subject worthy of investigation.

I am, Sirs, yours faithfully,
JOHN HADDON, M.D. Edin.
Denholm, Hawick, Feb 11th 1902.

## "WHAT'S WHAT."

*To the Editors of* THE LANCET.

SIRS,—As you have devoted a column of your valuable journal to the exposition of Mr. W. Watson Cheyne's point of view, and the correspondence he had with me with regard to the Appendix on London Medical Men in "What's What," I trust that you will have the fairness to allow me a brief space in which to state my own point of view in this matter. And this is the more desirable since the question appears to be one which greatly exercises the medical profession, and concerning which, not Mr. Cheyne only, but several other surgeons have addressed to me complaints.

First allow me to state the exact offence complained of. It is that I have printed a favourable opinion, which I state is derived from personal experience, concerning some twelve surgeons and doctors, most of them being well-known specialists. I have expressly limited my words by the following qualifications: "We do not suggest that the doctors named hereafter are superior to their fellows; we simply state that we have had experience of them as capable men in the various maladies alluded to, and that we should not hesitate to employ them ourselves."

Now, Sirs, I venture to assert that a similar statement, so limited, made concerning the members of any other occupation or business known to men would not have been considered annoying, improper, or in any way objectionable. It must be remembered that with regard to none of the gentlemen mentioned *is* there a word calculated to give pain or to express disapproval. My remarks are entirely confined to saying—I have had experience which justifies me in stating that those who go to A, B, or C for the cure of such and such diseases will go to men who are capable in their profession.

Can it be maintained—excluding the question of medical etiquette, with which at present I have nothing to do, and with which, indeed, a layman has no right to concern himself,—can it be maintained, I say, that to afford the public such information is in itself improper? Consider the record of any great man's illness and the newspaper comments on the skill and devotion of this or that medical attendant. Has anyone ever asserted that such comments were objectionable? Consider the biographical sketches of men such as Sir Henry Thompson or the late Sir Andrew Clark, in which are recorded, not only their abilities, but the steps by which they attained eminence. Has any objection ever been taken to the publication of these, though their very essence is laudation? Why, then, should it be taken to the Appendix of "What's What," which is clearly conceived in the interests of the public? The answer is to be found in the last letter which you publish from Mr. Watson Cheyne—that to the *Medical Times*. In that letter Mr. Cheyne states, with pardonable heat, that he has been unjustly suspected of self-advertisement, and he asserts that there is no reason why he should be so suspected. I most heartily agree with him; I go still further and say that such suspicion is as ridiculous as it is unjust—is absolutely incorrect and entirely unwarranted. There is no shadow of ground which could justify such assertion.

But, Sirs, I must go a step further: not only is this the case with regard to Mr. Watson Cheyne, it is also the case with regard to Mr. Harry Quilter. I am not a stranger to the public; it is more than a quarter of a century since I began to write continuously in books and newspapers, and opportunities have not been lacking to me, if my bent had been in that direction, of advertising my friends or calumniating my enemies. As a writer on the most important daily and weekly journals in England, as the editor of a well-known review, and as a constant contributor to magazines and newspapers of high standing, my words have been continually before the public, my opinions have been plainly expressed, frequently challenged, and as frequently defended. But no critic, however bitter, no adversary, however unjust, has ever said during the last quarter of a century that I wrote in the interests of advertisement, that I stated as facts what I did not believe.

Surely, Sirs, *I* have a right, with such a record, to resent this accusation even more strenuously than Mr. Watson Cheyne. Indeed, I have more ground for resenting it, for my whole life has afforded proof that it is false. In truth, it *is* a "dirty" suspicion, unworthy of a decent newspaper, and one for which there is no redress. It is true that no one who knows the gentlemen referred to would believe that they *paid me to praise them, and no one who knows me will believe that I was so paid. But the* majority of readers will know neither of us, and so this "pseudonymous anonymuncule," as Charles Reade would have called him, and his malicious insinuations will doubtless prejudice the minds of many envious and suspicious persons.

One last word, on the question which lies at the root of this matter—that of the medical etiquette, [illegible] forbids.

highest skill has designed for those in present use, or that a scheme of management by one authority would remove the stigma. It is also a question which is by no means capable of one answer whether the county council or guardians of the Poor-law district be the most efficient authority. There is no doubt, however, of the ability and of the power of the county council to take over this scheme, but, on the other hand, the "burden of insanity" in the maintenance of over 20,000 insane persons at a cost of considerably more than £500,000 a year is considerably lightened by the guardians who, through an already existing channel, collect the payments made by the relatives and those legally bound to them according to their means. If the guardians are to be superseded then considerable changes in the present Poor-law system become a necessity, but the trend of public opinion seems to be in opposition to the further centralising authority of lay officials. Your leader writer does not appear to appreciate that what may be suitable and to the point in the case of Edinburgh with its population of only 300,000 may be, and possibly will be, very inappropriate, if not impracticable, for the county of London with its area of 120 square miles and a population of nearly 5,000,000.

The Poor-law infirmaries have done much to lessen the stigma of insanity and Dr. Toogood's statistics support his assertion to this effect, but he admits that it may be in part unavoidable, as county asylum accommodation was not possible; but is the "stigma of insanity" less poignant than the "stigma of pauperism," neither of which would, I venture to think, be removed by the establishment of rate-aided "reception houses"? A strong reaction is setting in against the superfluous outlay which has characterised public asylum construction in the past, and the present tendency to spend for the cure of those who may recover is adequately reflected in the last report of the Lunacy Commissioners who emphasise their determination to advise the Secretary of State to refuse his approval of all plans in which there is an obvious departure from this principle.

As supplementing the scheme which Dr. Toogood, in THE LANCET of Feb. 8th, p. 403, recommends for the Poor-law infirmaries I am of opinion that a much wider question is involved than is now under consideration for London, and I should suggest adding to the pathological and clinical staff of our present asylums, and the construction for every asylum of a "hospital" with every "suitable appliance for a psychiatric clinic" into which the acute and the recoverable cases can be received and from which—after a reasonable interval—those deemed incurable can be removed into a less expensive, but still "safe, bright, secure, and adequate" home. In this way interest and hope can be instilled into the work of those whose lot lies in ministering to those afflicted with this most distressing disease and whose incessant intercourse with this class leads not infrequently to painful consequences.

I remain, Sirs, your obedient servant,

Feb. 18th, 1900. EFFICIENCY.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*Further Increase of the Plague Epidemic.—Increase in the Indian Medical Service.—The Population of Bombay.—Memorial to the late Surgeon-General Harvey, C.B.—A Parsi Sanatorium for the Sick Poor.—Antidotes to Snake Poison.—Small-pox in Simla.*

THE increase in plague mortality this week is general throughout India. The total is 11,445, against 9204 for the previous seven days. Bombay city returns 311, against 296, and a general mortality of 1118, equal to a death-rate of over 70 per 1000 per annum. The Presidency returns 4622 deaths from plague, an increase of over 1000; the Madras Presidency 622, against 590; Bengal Presidency 829, against 593; Mysore 604, against 653; North-west Provinces and Oudh 972, against 829; the Punjab 3040, against 2379; and Kashmir 316, against 257. Calcutta returns 61 deaths and Karachi 41. The epidemic is still raging in Poona where the deaths are nearly 50 each day, but for some unknown reason the weekly figures are not published. The figures for the past few weeks show that the disease is spreading in Bengal and Calcutta, in the Punjab, in Bombay city, in the Madras Presidency, and in the North-west Provinces. If previous experience is of any avail the next month or so will show the highest mortality from plague that has occurred since its introduction in 1896.

An increase of 26 officers has been sanctioned for the Indian Medical Service to meet civil requirements.

The final report on the census in Bombay city has been issued and shows a population for the island of 776,006. It is estimated that 114,000 persons have died from plague during the past five years. The density of the population is shown by the districts of Kumbarwhada having 598 persons to the acre and the district of Khara Talao 536 persons to the acre. The district of Mandvi, where plague started and where it has always been so virulent, is chiefly occupied by Jains, and it is estimated that whereas formerly they formed 3 per cent. of the population they now form only 1 per cent. It is a peculiar feature of their religion that they will not destroy any living thing and it is this district of Mandvi which has been overrun with rats, probably on account of the large number of its grain stores. Deaths from kala-azar in Assam have diminished considerably. The district of Sylhet, where the malady first made its appearance in 1893, is suffering from a mild type only, and in Nowgong the deaths have fallen from 12,012 in 1897 to 4661 last year.

It has been decided to start a subscription list for a memorial to the late Surgeon-General Harvey, C.B., Director-General of the Indian Medical Service, but the exact form of the memorial has not yet been fixed.

The Parsis of Bombay city have lately opened a sanatorium on Camballa Hill for their sick poor. The building will accommodate 36 families—12 on each floor, and each will have a sitting-room and bedroom with bath-room and kitchen. It has been constructed on modern principles and with the best sanitary appliances, and a special feature consists in the adoption of bacteriological tanks for the disposal of sewage sullage and waste water upon the plans of the installation which have been so successful at the Matunga Leper Asylum. The sick poor from the congested and unhealthy parts of the city will thus have the benefit of a change of air and healthy surroundings.

According to the researches of Captain Lamb we possess an antidote to cobra poison in Dr. Calmette's antivenin, but the latter is quite useless against the Daboia poison.

A severe outbreak of small-pox has occurred in Simla.

Calcutta, Jan. 30th.

## DENGUE AND PLAGUE IN THE NEAR EAST: THE PLAGUE IN BAGDAD.

(BY THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

REPORTS from the sanitary officers of Beirut and Tripoli show that in both these Syrian ports dengue has recently been rather severely epidemic. In Beirut the outbreak lasted some two months, and by the middle of December had almost completely disappeared. The large majority of the inhabitants were attacked, but the disease was most troublesome in old people and in persons the subject of malarial cachexia or of gastro-intestinal troubles. The number of deaths attributed to it were not large. Relapses appear to have been remarkably and unusually common, and in the hospitals some examples were seen in which the acute symptoms reappeared not only for the second but even for the third time after quite short intervals. The outbreak at Tripoli appears to have been equally general. In many families every member of the household was attacked and in most houses there were multiple cases. This epidemic appears to have synchronised with that at Beirut. The last report, dated Nov. 24th, stated that the outbreak was on the wane. In connexion with these outbreaks it is of interest to note that in Constantinople itself a few isolated cases clinically resembling dengue have recently occurred, but there has been no general epidemic.

Since the date of my last letter to THE LANCET[1] plague has shown but little activity in the Near East. In Constantinople itself, after the fatal case at Yakadjik on Nov. 5th, no other case occurred until near the end of that month. The patient in this instance was a Caucasian student, aged 16 years, who lived in a room over a casino called "The Caucasus," in the Karabash quarter at Top-Khané. He was said to have been taken ill on Nov. 25th, but he only sought advice on the 27th. The symptoms, as and quite a different law for Camberwell. It is no more justifiable for outsiders to advertise the former than it is for the latter to advertise themselves. That is the only argument which the *Medical Times* has emphasised, and I submit that it is irrefutable.—I am, Sirs, yours faithfully,

---

## THE SCHOTT TREATMENT OF CHRONIC CARDIAC DISEASE.

*To the Editors of* The Lancet.

Sirs,—In an annotation in The Lancet of Jan. 11th, p. 110, in speaking of a pamphlet entitled, "Personal Observations and Comments on Bad Nauheim and the Schott Treatment," written by Dr. O. Turner of Butte City, Montana, which first appeared in the *Chicago Clinic* (December, 1900), you say, "We understand that this pamphlet *has been widely distributed, and we think that* Professor Schott should, in justice to himself and the many English physicians who send patients to Bad Nauheim to be placed under his care, at once take steps to challenge, and we feel sure to refute, the grave professional charges which are brought against him." Had you known the facts in this case I do not think that you would have considered it important for Professor Schott to answer Dr. *Turner's attacks on his professional character* You could not have been aware, however, that a mutilated fragment of my challenge and refutation of the grave professional charges brought against Professor Schott had appeared in the *Chicago Clinic* a short time before your notice was published

My letter as published was so much abridged that some important corrections of Dr. Turner's statements were entirely omitted. This will be rectified in a *pamphlet* shortly to appear where full justice will be done to Dr. Turner's statements, and the methods which have been pursued in distributing the same. The character of Dr. Turner's violent personal attack upon Professor Schott is unworthy of a professional gentleman, even were it supported by facts. Resting as it does, however, upon false statements, it cannot be deemed an effort to enlighten the profession and add to medical accuracy by sound and temperate criticism of error, but is a base attempt to darken council and destroy the reputation of a professional colleague who is doing curative work of great value. Were Dr. Turner not safely hidden in the far-off mountains of Montana, the best answer Professor Schott could make would be an action for criminal libel against the inventor and circulator of this precious pamphlet. My faith in the traditional fairness and justice of The Lancet which have never failed is my excuse for addressing you.

I am, Sirs, yours faithfully,

Rome, Feb. 8th, 1902. W. W. Baldwin, A.M., M.D.

## A POINT FOR PUBLIC VACCINATORS.

*To the Editors of* The Lancet.

Sirs,—I inclose a further communication from the General Post Office, *re* my last letter asking for further details of the regulations under which I am forbidden to wire for vaccine in an emergency or scare, free. As you will perceive, the Board of Agriculture takes more care over its swine and policemen than at present our Local Government Board does over small-pox and its medical officers, for surely it *does* appear monstrous that the Board of Agriculture by arrangement with the General Post Office pays for all reports sent by its policemen on wire, and yet the Local Government Board does not recognise our efforts to re-assure the public in a time of "official notices *re* small-pox" scares, &c., by endeavouring to obtain lymph quickly when the distance is great from London. As in your editorial comment on my letter, I admit that the law is against me, and knowing the futility of kicking against the pricks, I have paid for the telegram. All through I have been only actuated by *the fact that I* thought that my brother practitioners might not know the point which I have endeavoured to elucidate, and not having before seen the point raised might feel, as I do, that the Local Government Board would arrange facilities for quick transit of lymph when small-pox is spreading. Hoping that perhaps my feeble efforts to find out the true position may one day bear fruit, and thanking you for your kind consideration in sparing me space in The Lancet,

I am, Sirs, yours faithfully,

Henry T. Whitling, M.B., B.S. Durh., &c.

Husband Bosworth, Rugby, Feb. 14th, 1902.

[Inclosure].

General Post Office, London, Feb. 12th, 1902.

Sir,—With reference to your further letter of the 2nd instant respecting the question of payment for telegrams sent by you to the Local Government Board, I am directed by the Postmaster-General to explain that, as already stated, only officers of Government departments are entitled to send telegrams free of charge. You are under a misapprehension in supposing that telegrams sent by the police to the Board of Agriculture are dealt with by this department free of charge. By arrangement with the Board, such telegrams are accepted without payment at the time of despatch, but they are subsequently paid for by the Board.

Similarly the postage upon unpaid letters addressed to the Board of Agriculture is charged against the Board in the official account, and only such letters are entitled to pass without prepayment of postage under this privilege as are sent upon the public business. It is not considered that letters of application to the Local Government Board for lymph, such as you mention, are letters entitled to the privilege in question, and they should be prepaid with postage, therefore, in the ordinary way. I am, Sir, your obedient servant,

H. F. Whitling, Esq., M.B., B.Sc. John Ardron,

## "AUDI ALTERAM PARTEM."

*To the Editors of* The Lancet.

Sirs,—It is due to me that it should be known that I replied fully to Dr. Latham's last communication, and that my letter was returned to me for further consideration, its tone not commending itself to the editors. I decline to modify its tone and cannot help feeling that as no editor is expected to accept responsibility for the statements of his correspondents the right should have been conceded to me of supporting my case by all fair and reasonable means.

I am, Sirs, yours faithfully,

Nottingham, Feb. 19th, 1902. Edward Dean Marriott.

⁂ Our correspondence columns are headed with an avowal of the impartiality which we strive to maintain. Mr. Marriott's letter was returned not because it contained statements for which we declined to take responsibility, but because both from its tone and its contents it invited an acrimonious discussion for which we did not care to find space.—Ed. L.

## THE EDINBURGH SCHEME FOR A PSYCHIATRIC CLINIC.

*To the Editors of* The Lancet.

Sirs,—The writer of your leading article on "The Edinburgh Scheme for a Psychiatric Clinic," in The Lancet of Feb 1st, p 318, somewhat fails to realise that *mental disease* has its bodily aspect, and that marked physical impairment is an almost inevitable accompaniment of acute mental disorder. To collect the insane either together in one "reception house" or in groups of houses for the purpose of a psychiatric clinic would (at least for London) mean the compulsory sale of Bethlem and St. Luke's Hospitals, or, failing this, the erection of new buildings upon land, both of which would be equally costly and undesirable. Those who are interested in the welfare of the insane have repeatedly advised the removal of these institutions from the heart of London into some more salubrious district where light and air, outdoor exercise, and healthy occupations could be indulged in daily—which is impossible during many days of winter fog and mist such as now enshroud the city; yet the influence of The Lancet is cast in a contrary direction

It is probably not known to the great bulk of your readers that the present asylums of London are already the "psychiatric clinics" of the medical schools, that they are situated upon healthy sites in the environs at not inconvenient distances from the centre of London, and that they have ample and extensive park-like grounds for recreation These institutions received over 3500 new admissions last year, so that the total accommodation of *Bethlem and St. Luke's Hospitals with their aggregate of* only 350 beds—and I assume that they or an equivalent could be taken over as "reception houses"—would be totally inadequate. Further, if the anxiety be for the lot of the acutely insane and if consideration be felt in regard to the stigma appertaining to insanity, it is questionable whether more suitable sites and buildings could be obtained than the be seen how infinitely small the proportion of small-pox cases is to the number of inhabitants. Meanwhile the ill wind blows and the good follows in the prevalence of vaccination both by public vaccinators and by general practitioners throughout the country. The chairman of the Health Committee has shown a laudable example in being vaccinated himself, and it is noticeable that a large number of public functionaries have also submitted to the same precautionary measure. The medical officer of health has suggested also that the committee should recommend that the Infectious Diseases (Notification) Act, 1889, shall apply within the city to chicken-pox as if such disease had been specifically mentioned in the Act. No doubt this recommendation will be adopted as a wise provision for discrimination and prevention of the spread of disease.

### *Unqualified Dentists*

Some discussion has arisen on the question of the registration of all who practise dentistry. Birmingham suffers, as most towns do, from the presence of a large number of advertising dentists. There are difficulties in placing the names of those upon the Register who have not gone through the necessary curriculum; but the number of those practising before the adoption of the Register is now yearly getting fewer, and in time the question will largely settle itself. The mechanical part of dentistry must often be worked out under the direction of some superior; the surgical part is inevitably only to be acquired by long and patient study in a recognised school of teaching. The Birmingham School of Dentistry is an exceedingly good one and abounds in very able and competent teachers.

Feb. 18th.

## LIVERPOOL.

(From our own Correspondent.)

### *The Liverpool School of Tropical Medicine: the Anti-mosquito Campaign.*

Arrangements have been made for Major Ronald Ross, F.R.S., late I.M.S., Walter Myers lecturer in the Liverpool School of Tropical Medicine, to proceed for the third time to Freetown, Sierra Leone, to assist in the work which is being vigorously undertaken in West Africa against malaria and mosquitoes. Major Ross will sail from Liverpool on Feb. 22nd. The expedition which he is going to rejoin, the fifth to be organised by the Liverpool School of Tropical Medicine, went out early in last year under Major Ross's direction with Dr. A. Logan Taylor. The work of the expedition is being carried on with energy. Dr. Latchmore, the medical officer of the Princess Christian Hospital in Sierra Leone, in his report, says that it is at present too early to say anything about the decrease of disease there, because the members of the expedition have only been at work eight months, and because it is very difficult to know whether such cases of fever as have occurred are simply relapses in old cases or fresh cases in which infection had been contracted since the beginning of operations. He adds that it can only be said guardedly that during this time there have been very few cases of malaria reported and that the health of the Europeans in the town has improved. He also says that there can be absolutely no doubt that the expeditions are doing a great work for the health of West Africa. Dr. Logan Taylor has succeeded in destroying a large area of the breeding ground of mosquitoes, and in consequence there has been a great decrease in the number of mosquitoes in the houses. Some houses have been practically free from anopheletes for weeks, whilst others contain very few. He also states that anti-malaria work is being pushed on up country.

### *The Royal Southern Hospital: the Ward for Tropical Diseases.*

The ward in the hospital devoted to the reception of patients suffering from tropical diseases in connexion with the Liverpool School of Tropical Medicine continues to do much useful work. 130 cases were admitted in 1901. The following nationalities were represented: English, Irish, Scotch, Welsh, Australian, Canadian, Spanish, Portuguese, French, West Indian, African, Swedish, Norwegian, Danish, Dutch, and East Indian. 18 were Lascars. There were 94 cases of malarial fever, 10 of dysentery, six of beri-beri, one of (tropical) abscess of the liver, and one of enlarged spleen. There were 11 deaths. In order to enhance still further the value of the work an out-patient department has been opened which is under the care of Major Ross and Dr. H. E. Annett. The sixtieth annual report of the committee of the Royal Southern Hospital states that the debit balance stands now at £5186 11*s.* 4*d.* £2139 had been received from the ex-Lord Mayor's Hospital Century Fund, and £2010 from the Hospital Saturday and Sunday Fund. The number of patients treated in the hospital during 1901 was 12,964, of which 2351 were in-patients and 10,613 out-patients. The total number of attendances was 46,343, against 44,175 in the previous year, showing an increase of 2168. The ambulance brought in 381 cases, the total number relieved by that means since the inauguration of the service in 1887 being 5875. The average number of beds occupied during the year was 190, the greatest number of in-patients at one time being 203. The number of deaths was 200, of which 60 occurred within 24 hours of admission; 18 persons who were brought in dead were not included in the above.

### *Small-pox in Liverpool: Deputation to the President of the Local Government Board.*

The latest report of the medical officer of health of Liverpool places the number of patients suffering from small-pox at 42. A fortnight ago there were only 18 cases, but the increase need not be considered alarming as the addition to that number was largely caused by the arrival of the s.s. *Kansas* from Boston on Feb. 6th, having on board 14 persons suffering from small-pox. The utmost vigilance was exercised by the port sanitary authorities to prevent the ship from coming in contact with any other vessel, and the *Kansas* proceeded up to the Sloyne, a part of the Mersey at some distance from the landing-stage, whilst the patients were removed to the port sanitary hospital. The latest patient is a man who landed nearly three weeks ago from the steamer *Devonian*, also from Boston. The illness was of a type so mild that he did not suspect the nature of it. He presented himself at one of the general hospitals of the city on Sunday last in regard to some "spots" on his body, when the nature of the disease was determined. This individual, in the opinion of the authorities, had no doubt been the source of infection to two of the cases previously reported in which infection at that time had not been traced.—Mr. Walter Long (the President of the Local Government Board) will receive a deputation from the Port Sanitary Authority of Liverpool on Feb. 20th in reference to the difficulty experienced by that body in dealing with persons who had been exposed to the risk of small-pox on board vessels arriving in Liverpool.

Feb. 18th.

## WALES AND WESTERN COUNTIES.

(From our own Correspondents.)

### *Small-pox.*

In Ystalyfera, near Swansea, small-pox appears to be dying out, but in the borough of Swansea fresh cases are occurring, one having been reported on Feb. 10th and two on Feb. 15th.—The Swansea Corporation discussed on Feb. 12th the desirability of adding chicken-pox to the list of diseases notifiable in the borough. Although formal notice had been given in accordance with the provisions of the Infectious Disease (Notification) Act, 1889, the motion giving effect to the addition of chicken-pox was lost in favour of one instructing the town clerk to communicate with the medical men practising in the town, respectfully requesting them to seek the advice of the medical officer of health in all doubtful cases of measles or chicken-pox coming under their care.—In Cardiff at present there has occurred only one case of small-pox, the patient being a man who was admitted to the tramp ward of the workhouse on Feb. 4th. On the 5th he went into the workhouse infirmary and on the following day was found to be suffering from small-pox and was removed to the isolation hospital. The man had never been vaccinated. At a meeting of the board of guardians the chairman of the board animadverted upon the removal of the patient when he fell ill to the infirmary instead of to the isolation ward. It seems almost impossible for a layman to understand that the diagnosis of small-pox cannot be made on the first day of the disease, and if the suggestion that every ailing tramp should be placed in an described, were fairly characteristic of an attack of plague with bubo in the left groin. The fact that this patient was a Caucasian and that some cases of plague had occurred shortly before at Batoum in the Caucasus led to the suggestion that this was an instance of fresh importation of infection from Batoum. But the fact that the house where the boy sickened was in the same quarter of this city where so many of the earlier cases of plague had occurred lent far greater probability to the view that the case was of indigenous origin. No other case of plague has since come to the knowledge of the authorities in Constantinople.

In Batoum and Odessa a few cases of plague and others of "suspected" plague occurred between the end of October and the beginning of December, but very few accurate details have as yet come to light as to their number, origin, or character. The Ottoman Board of Health imposed 10 days' quarantine against Batoum on Oct. 30th and removed it on Nov. 10th, re-imposed it on Dec. 10th and removed it on the 18th. Against Odessa 48 hours' observation with disinfection was imposed on Nov. 12th and removed on the 22nd.

In Smyrna no known case of plague occurred between the middle of September and the end of the year. On Dec. 21st a waiter in a restaurant on the Smyrna quays fell ill and later examination proved that this was a fresh case of plague. On Jan. 16th a second case was reported, the patient in this instance also was a waiter employed at a café situated on the quays. In both instances there was bacteriological proof that the diagnosis of plague was correct. It is difficult to account for these cases. The history of plague in Smyrna during the past year has been briefly as follows. In December, 1900, a small epidemic of plague pneumonia occurred in a village close to the town causing the death of three whole families; in January a case of bubonic plague occurred in the town itself, another followed in the month of May, and a third in September. It is not easy to account for these long plague-free intervals otherwise than by supposing each case to be due to a fresh importation of infection. Smyrna is in constant relations with Constantinople and with Alexandria, in both of which plague has been present through the greater part of the past summer and autumn.

On Jan. 3rd a plague case was discovered at Beirut on the Syrian coast. The patient was a native of Bagdad and had travelled from Bagdad to Beirut, stopping a certain time (the length of which is at present unknown) at Damascus *en route*. He fell ill the day of his arrival at Beirut. This case presents many points of interest. As he is said to have fallen ill on the day of his arrival it is scarcely possible that he can have contracted the disease in Beirut itself. He came originally from Bagdad, and as will be shown later plague has been present in Bagdad certainly for several weeks and possibly for many months. Later reports will, it is hoped, throw more light on this case, particularly as to the length of the interval between the patient's leaving Bagdad and his arrival in Beirut.

On Jan. 20th the sanitary officer at Bagdad telegraphed to the Board of Health in Constantinople that an outbreak of plague of some severity had occurred in that city. Up to that date eight known cases, of which four had proved fatal, had come to the knowledge of the authorities. A later telegram reports two more cases and three deaths, bringing the totals to 10 cases with seven deaths. Of the origin of this outbreak nothing is at present known with certainty. The sanitary officer's report states that rumours had been current for some time that a suspicious disease existed in the Abou Seiffdin quarter of Bagdad, but that no one ventured to point out to him the houses affected. As long ago as Dec. 9th he wrote to the Vali asking that an order might be given to the medical staff to inquire into the outbreak, but apparently nothing was done. The first certain case seen by him was on Jan. 17th. The suspected quarter of the city was the Jewish quarter and it is noteworthy that all the first eight cases were of the Jewish religion. In connexion with this outbreak the sanitary history of Bagdad during the past year is of the greatest possible interest. In May of last year a limited outbreak of plague occurred in the Sadrieh quarter of that city. So far as was known the disease then died out, but evidence has since come to light that this may not have been the case and that plague may have lingered on in Bagdad from then until the present day. In a report of the sanitary officer there, dated July 29th, it was stated that in June last rumours were already current of several cases of suspicious disease in the Bab el Chah and Sadrieh quarters of the city. On June 13th he and another practitioner "penetrated" into these quarters and saw three patients with bubonic symptoms. The *mouhtars, imams* and other local notables denied the existence of anything unusual, but on the 14th two more cases were seen, and on the 15th one case. No subsequent cases could be observed, because the people had become suspicious of the medical men's visits and refused to report any more. The detailed description of these six cases shows that in each there were slight fever, one or more enlarged glands, and a short illness always ending in recovery.

A later report dated Nov. 28th last stated that similar cases of fever with enlarged glands had continued to appear from time to time in Bagdad in different parts of the town, and it was added that within the 10 or 20 days preceding the date of the report as many as half a score of such cases had been seen in a Jewish quarter of the city. It is in this quarter that the present outbreak of the plague has occurred. It is difficult in reviewing this brief history not to suppose that these cases of mild glandular fever may have been cases of mild or ambulant plague, and that the present outbreak of the severe form of the disease is but a revival of the infection remaining from the outbreak there in May last.

The measures decreed by the Board of Health to control this epidemic are briefly as follows. Two temporary lazarets of tents have been formed, the one to the north, at Beni Said Han, and the other to the south-west, on the Redvanieh Canal. Passengers have to undergo here five days' quarantine with daily exposure of their goods to the sun. Ships leaving Bagdad (by the Tigris) for the south undergo five days' quarantine at Gararah (close to Bagdad). Before loading such ships have to have their rats destroyed by sulphur fumigation. On arriving at Basra (near the mouth of the river) these ships have to go to the lazaret there in order that the clothes and effects of the passengers and crew may be disinfected in the stove. Cavalry patrols have been ordered to patrol the country between Bagdad and the two lazarets named above. The carriage of dead bodies from Bagdad to the Shiite Holy Places of Kerbela and Nedjef is prohibited for the present.

Constantinople, Feb. 1st, 1902.

## BIRMINGHAM

(FROM OUR OWN CORRESPONDENT.)

### *The Welsh Water Scheme.*

WHEN the corporation of Birmingham embarked upon the scheme of a water-supply from the Elan valley they were contented with the prospect placed before them. The estimated expenditure was certainly very large, but it was considered to be amply sufficient for the object in view. The Parliamentary estimate for the first instalment was £3,755,360. Years have gone by, the works have steadily progressed, and as surely the expenditure has grown in a ratio far exceeding the expectations of the Water Committee of the Town Council. Even the most sanguine promoters of the project have to confess that they were unprepared for the enormous increase in the figures which has been laid before the Council. A report has been issued in which it is shown that the present estimate is £5,884,918, an excess of £2,129,558. This is a gigantic sum and the amount is looked upon with surprise mingled with indignation. The heavily burdened and patient ratepayer has to bear this extra load with philosophic resignation. Protest is useless, but the "man in the street" criticises freely and wonders how such a prodigious increase on the original estimate could have occurred—more particularly when he recollects that eminent geologists, leading engineers, and a host of scientific experts were engaged upon the work for a long time before the estimates were made out.

### *Small-pox.*

A single case of small-pox is the total of the outbreak so far in Birmingham. As one swallow does not make a summer, so it may be inferred that one case may not be the beginning of an epidemic. Still it is curious to observe how fear takes hold of many who dread an epidemic. In view of this solitary instance it is asserted that many country people refuse to come into the city, and speak with bated breath of the presence of small-pox in our midst. When reflection is allowed to take the place of panic it will six most dreaded infectious diseases—viz., measles, whooping-cough, diphtheria, enteric fever, erysipelas, scarlet fever, and small-pox Sir Henry Littlejohn, in his report for the year 1899, had shown that out of 574 deaths due to pulmonary consumption three-fifths of the victims inhabited houses of one, two, or three rooms. Presumably most of these had been ratepayers who if they had become ill with one of the fevers would have been entitled to the benefits of the city hospital. The municipality had, however, made no attempt to deal with cases of consumption even though it was a much more deadly infectious disease than any which it took charge of in the city hospital. If the town was to deal with those cases it must do so upon purely public and not on benevolent grounds. It was impossible to isolate the patients in all cases of consumption, but they might provide for cases beyond the range of cure and at the stage of the disease which was most dangerous for the community. The committee had made a suggestion that 100 beds should be fitted up in the present city hospital when the new hospital at Colinton had been completed, but it might prove to be more profitable to sell the old hospital and to provide a site elsewhere. What the committee desired meanwhile was that the council should, without committing itself as to site and other details, approve of the recommendation to include consumption among the notifiable diseases and that the council should further generally approve of the recommendation to provide accommodation for 100 beds for the reception of the most advanced cases of consumption. Treasurer Cranston, in seconding the motion, believed that whatever sum was required would be freely and frankly paid by the citizens in return for the benefit which they would get. The probable annual cost of notification, estimated at 2*s.* 6*d.* a head, would amount to £750, and a similar sum would be required for examining sputum. Mr. Clark proposed an amendment to the effect that arrangements should be made for voluntary but not compulsory notification. He thought that compulsory notification interfered too much with the rights and liberties of the people. On a division, after a four hours' sitting, 10 voted for the motion and 20 for the amendment.

### *Royal Society of Edinburgh.*

A meeting of the Royal Society of Edinburgh was held on Feb. 17th, Professor Geikie, vice-president, being in the chair. Major W B. Bannerman, I.M.S., superintendent of the Plague Research Laboratory at Parel, gave an account of the work carried on there under Professor Haffkine, the director-in-chief. Professor Fraser doubted whether plague epidemics could be stayed by the use of plague prophylactics, and urged that improvements should be brought about in the dwellings of the people. Major Bannerman, in reply, wished that Professor Fraser would use his influence to get a representative of the medical profession attached to the Legislative Council of the Viceroy of India.

### *Small-pox in Glasgow.*

There has been a somewhat rapid extension of the epidemic, which was, however, not altogether unexpected, and is not in any sense alarming. The number of cases under treatment has increased to 133, and even this does not fully represent the recent activity of the outbreak, as many convalescents have been dismissed from the hospital. On Feb 14th the new cases numbered 20; on the 15th, 39; on the 16th, 26; and on the 17th, 18. For the most part the cases have been of a mild type. At a meeting of the town council on Feb. 18th one of the medical members, in discussing the small-pox outbreak, drew attention to the large proportion of cases occurring in the east-end of the city, and argued that the explanation of this was the proximity of the small-pox hospital. This statement aroused some indignation and was generally condemned as neither warranted by the facts nor politic in the circumstances. The Lord Provost made an urgent appeal to the citizens to adopt the practice of revaccination. He stated that some 10 to 20 per cent. of the population even now remained unvaccinated, and he pointed these out as a danger to the whole community.

### *Glasgow University.*

The University Court met on Feb. 13th. The principal made sympathetic reference to the death of Professor Adamson which has caused general distress and deep regret throughout the whole university. It was announced that the senate has appointed Monsieur Emile Bontroux, Professor of the History of Modern Philosophy in the Sorbonne, Paris, to be lecturer on the Gifford foundation for the sessions 1903–4 and 1904–5.—A distinctive robe has been designed for members of the court and this was formally approved.—The court has received a letter from the secretaries of the Muirhead College proposing coöperation with the university regarding the medical education of women; the letter was referred to a special committee.

Feb. 18th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Small-pox in Dublin.*

No fresh case of small-pox has appeared in Dublin, while the three patients isolated in the convalescent home at Findlas continue to go on well. Sir Charles Cameron has written to the daily papers stating that the Public Health Committee has resolved to recommend the corporation to add chicken-pox to the schedule of infectious diseases which are notifiable. He appeals to medical practitioners kindly to report this disease even before notification has become compulsory.

### *Extraordinary Accident to a Coroner's Jury.*

On Feb. 8th an extraordinary accident occurred at Newlands, three miles from Naas, in county Kildare. A man died on the previous day from the accidental stab of a pitchfork in the leg, and Dr. M. F. Kenna, the coroner for South Kildare, went to the place the next day to hold an inquest. The jury first proceeded to "view the body," which lay in a loft over a byre. The floor was a shaky one, and as soon as the twelfth juryman put his foot on it the entire fabric gave way precipitating the 12 men down on to the cattle below. The portion of the floor on which the corpse lay remained intact, but all the rest fell. The distance the jury fell was only seven feet, and, fortunately, beyond a few contusions, received while struggling among the cattle, no casualty occurred. The noise and confusion within the byre before the door was opened by the police to liberate the men were indescribable. The cattle, frantic with fright, roared, the jurors shouted and swore, and in their struggles with the cattle banged against one another or rolled on the not over-clean floor of the cowshed. When released they presented a remarkable appearance, being covered from head to foot with manure, while the odour exhaled from them was anything but pleasant. After a time, however, the inquest was proceeded with and a verdict in accordance with the medical evidence was returned.

### *The Government and Vaccination.*

One of the most constant supporters of the present Government (the *Belfast Newsletter*) has a strong leading article in its issue of Feb. 18th in which it declares that it has "no sympathy whatever with the Government in this course of procedure"—that is, its opposition in the House of Lords on Feb. 17th to the Bill introduced by Lord Newton which sought to amend the Vaccination Act of 1898 by repealing the conscientious objector's clause of that Act. The *Belfast Newsletter* article blames the Government for its abject surrender to the so-called "conscientious objector" in 1898 as a most glaring blunder, and if, as it is stated, it was due to its desire to rush the Bill through by August 12th, then to resort to such methods of expediency is bad management of the business of the session. To abandon a principle approved of by the vast majority of the Members of the House of Commons in order to placate a small opposition because of the necessity of winding-up the session at a fixed date, is certainly poor statesmanship.

### *Irish University Education.*

A petition has been prepared for presentation to the chairman of the Irish University Commission on behalf of Roman Catholic laymen. It urges that of the various proposals submitted to the Royal Commission the best is to be found in the establishment and endowment of a college in Dublin for Roman Catholic students affiliated to the University of Dublin, which should be, equally with Trinity College, a constituent college of the University with adequate representation on the governing body of the University. Those signing this petition—and it is said that it springs largely from members of the legal profession living in Dublin—argue that no scheme of university education in Ireland will be satisfactory unless it affords Roman Catholics the opportunity of taking the best degree to be obtained in isolation ward is to be carried out many more such wards must be erected speedily, for it is obvious that if there is more than one patient in the ward it ceases to serve the purpose of isolation.—At Gloucester there is one case of small-pox, the patient being a sailor who had come from Bristol. There has recently been erected at Gloucester, at a cost of about £15,000, a very well-equipped permanent isolation hospital with accommodation for 28 patients in three pavilions.—A case of small-pox has occurred in a farmhouse about five miles from Hereford, the patient having contracted the disease in Liverpool.

### *Disinfection after Phthisis.*

In spite of the public meetings which have been held and the literature which has been scattered abroad in South Wales upon the subject of tuberculosis there appear to be still some members of sanitary authorities who are ignorant of the precautions necessary to combat the disease. After a death from consumption in Oystermouth, a district near to Swansea better known as the Mumbles, the medical officer of health, Mr. A. Lloyd Jones, very properly had the house in which the patient died disinfected—a proceeding which members of the district council characterised as quite unnecessary, and the chairman thought that the medical officer of health should be given an opportunity of stating his reasons for ordering the disinfection. When these reasons have been given the district councillors will perhaps realise that if they desire to attract visitors to their town they must encourage their officers to carry out these and similar precautionary measures.

### *Cardiff Infirmary.*

An appeal has been issued by the Board of Management of the Cardiff Infirmary for £5550 to carry out certain projected improvements in the infirmary buildings. The form of the appeal is novel in that the improvements desired are definitely stated and the approximate cost of each is specified. Among the most important are an accident receiving ward which is to cost £1000, a room for delirious patients to cost £50, and a mortuary at a cost of £25.

### *Attack upon a Medical Man.*

Mr. W. A. Reidy, a medical practitioner in Fleur-de-Lis, a Monmouthshire village near Cardiff, was subjected, though happily without serious consequences, to an alarming attack on Feb. 8th. On the evening of that day while sitting in his dining-room a bullet was fired through the window and window shutter and it fell at his feet. In connexion with the outrage a woman who had been a patient under the care of Mr. Reidy and whom a short time before he had refused to see is under remand

### *Isolation Accommodation in Worcestershire.*

A conference was held on Feb. 8th between the sanitary committee of the county council and the district councils of Worcestershire to consider what steps should be taken to prepare for an outbreak of small-pox. The population of the administrative county is 360,000 and there are within the county 13 urban and 17 rural districts. In only three of the urban and one of the rural districts, having a total population of 100,000 persons, is there any provision made for isolating small-pox. It was decided by the conference to recommend the county council to divide the county into six districts and to erect in each district an iron hospital with steam disinfector, &c. It is estimated that the cost of this scheme to the county will be about £3000, an amount equal to ½*d.* in the pound upon the assessable value of the county.

### *Gallant Action by a Medical Man.*

At St. Agnes coastguard station on Feb. 11th the divisional officer (Lieutenant R. Ayscough, R.N.) presented two coastguards with bronze medals and diplomas which were awarded to them by the Dutch Humane Society for rescuing one of the crew of the ship *Voorspoed* off Perran Beach, Cornwall, on March 7th, 1901. Mr. Frank Postlethwaite, M.R.C.S. Eng., L.S.A., of Perranporth, received a silver medal from the society for boarding the vessel to render assistance to the man.

### *Taunton and Somerset Hospital.*

The annual meeting of the subscribers of this institution was held on Feb 13th under the presidency of the Hon. E. W. Portman. The medical report stated that the number of in-patients discharged during 1901 as "cured or relieved" was 736, against 593 in 1900 4500 out-patients were treated, compared with 3968 in the previous year. The report mentioned that the recent appeal for £6500 for hospital improvements was liberally responded to, the sum of £6050 having been received already. During the past year the late Mr. R. B. West of Exeter had bequeathed £1000 to the institution. At the close of the meeting Major W. Barrett promised £400 towards the deficit on the building fund.

Feb 17th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Edinburgh University: Death of the Lord Rector.*

BY the death of the Marquis of Dufferin the University of Edinburgh has lost its Lord Rector. To those who were present at the rectorial address which he delivered in the M'Ewan Hall some months ago and who noted his profound anæmia and extreme debility the Marquis's death has been no surprise. On Feb 15th the Senatus of Edinburgh University gave expression to its sorrow at the death of the Lord Rector by holding a service in St. Giles's Cathedral at the hour of the funeral The students of the university through their Representative Council decided to give expression to their deep regret by holding a religious service in the M'Ewan Hall on the afternoon of Sunday, Feb. 16th. This service was largely attended and was presided over by the senior president of the Students' Representative Council. The meeting was addressed by the Rev. John Kelman, who dwelt upon the brilliant career and the high character of the deceased Lord Rector.

### *The late Dr R. Peel Ritchie.*

In THE LANCET of Feb. 15th, p. 481, I made reference to the death of Dr. R. Peel Ritchie. Preaching in St. Cuthbert's Church on the morning of Sunday, Feb. 16th, the officiating clergyman paid the following high tribute to his memory He said: "In his relation with us as a member and office-bearer he leaves behind him the memory of a pure, straightforward, and upright Christian gentleman. Amid the differences of opinion which arise in the work of life he was always clear in stating his views, but he cherished no feelings save those of brotherly charity and friendship between man and man. Essentially a public-spirited and deeply religious man he gave much of his time to the public service, especially on behalf of the suffering and the destitute. As an elder of the church he was always marked by his faithful devotion to duty, by his high-mindedness and sincere Christian principle." Reference was also made to Dr. Ritchie's strenuous labours in the cause of Church defence, a cause which lay very near his heart.

### *The late Charles Stuart, M.D., L.R.C.S. Edin*

By the death of Dr. C. Stuart of Chirnside, Berwickshire, the border counties have lost a well-known medical man. He was a graduate in medicine of Edinburgh University of the year 1846 and had practised in Chirnside since 1848. In addition to his medical interests Dr. Stuart was a lover of plants and flowers and devoted considerable attention to the production of new varieties by cross-fertilisation. He also wrote papers on the botany, archæology, ornithology, and meteorology of his district. He had retired from active work during the last few years of his life.

### *Edinburgh Town Council: Notification of Consumption.*

A special meeting of the Town Council of Edinburgh was held on Feb 12th to consider reports by the Public Health Committee recommending the magistrates and council, as the local authority, to consider the passing of a resolution that the notification of pulmonary consumption should be made compulsory within the district, and suggesting the provision of a hospital with 100 beds for consumptive patients. The meeting was well attended at the outset, but at the close only about 30 members were present. The motion was given by Mr. Lang Todd, convener of the Public Health Committee, and ran as follows.—

> (1) That the magistrates and town council, as local authority, resolved to meet on a date to be afterwards fixed in terms of the statute to pass a resolution that the Infectious Diseases Notification Act, 1889, shall apply to pulmonary consumption within their own district; and (2) that the magistrates and council generally approve of the suggestion that provision should be made for consumptive patients, but not exceeding 100 beds.

Mr. Todd discussed the hopefulness of the prospect in attempting the prevention of consumption, now that consumption was recognised to be not a hereditary but an infectious disease. He showed that the mortality from pulmonary consumption greatly exceeded the combined mortality from the

Government or municipal officials and as such are required to make a daily visit to each of their wards. They may engage in private practice, but only as consultants. The number of chief medical officers is as a rule much too small, so that each of them is responsible for the care of a great many patients—sometimes from 300 to 400, and in Berlin a few years ago the number of chief medical officers was doubled with the view of relieving this pressure. As a matter of fact, this system has answered well in every way; the intellectual portion of the public are quite satisfied with it as it stands, and among the physicians and surgeons of the municipal hospitals of Berlin and other German cities there are men of European fame. If, as the Socialist party desires, these gentlemen were debarred from private practice and compelled to devote themselves exclusively to their hospital duties, the majority of them would no doubt resign their hospital appointments, as their emoluments derived from private practice must be twenty times as great as their official salaries. In his reply to Herr Antrick, Count Posadowsky, the Secretary of State, said that all these charges and some others of a like kind which were made by the Socialist party were either unfounded or exaggerated, and without denying the occasional possibility of abuses, he maintained that isolated occurrences must not be treated as representative of the hospital system in general. German hospitals, especially those of Berlin, were celebrated for their medical staffs, and foreign medical men who had visited them on such occasions as the meetings of congresses, spoke of them with admiration. Count Posadowsky added that the debate was in any case a purely academical one, for the municipal hospitals were under the control of either the municipalities or the Governments of the individual States, so that the Imperial Government had nothing to do with the matter. It is not unlikely that this debate in Parliament may tend to deter patients from seeking hospital treatment The charges made against the hospitals do not for the most part rest on any foundation in fact and have caused much indignation in medical circles. The Berlin Municipal Council is the proper authority for dealing with such questions, and some of the members have announced that they will take steps to bring about an investigation.

### *Serum Treatment of Scarlet Fever.*

At a recent meeting of the Gesellschaft der Charité-Aerzte (Society of Medical Officers of the Charité Hospital) Professor von Leyden gave an account of experiments that had been made on the treatment of scarlet fever by injections of serum. Serum obtained from patients convalescent from scarlet fever was injected in 12 cases, the result being evidently favourable in three of them, less marked in eight, and inappreciable in one. The temperature decreased in one case on the third day, in two cases on the fourth day, in four cases on the fifth day, and in two cases on the sixth day. All the patients were adults. The quantity of serum injected was 10 cubic centimetres at first and 20 cubic centimetres afterwards. In the ensuing discussion Professor Heubner said that in order to test the efficacy of Professor von Leyden's serum it ought to be used in serious cases only, for mild cases might recover without any treatment. He also pointed out that injections of human serum were not free from the danger of transmitting syphilis or tuberculosis, and, moreover, that in the absence of any definite knowledge as to the special virus of scarlet fever it was impossible to ascertain by experiment whether the serum of convalescents contained an antitoxin or not. Professor von Leyden, in his reply, said that the last-mentioned objection was equally applicable to the serum treatment of diphtheria, the efficacy of which was nevertheless beyond question.

### *His Excellency Professor von Bergmann.*

Dr. von Bergmann, ordinary professor of surgery in Berlin University and director of the university surgical clinic, has been invested with the rank of Wirklicher Geheimer Rath (Real Privy Councillor). This dignity, which is the highest of its class in Germany, carries with it the title of Excellency and is as a rule conferred only on great officers of State and persons occupying important positions at Court, very few medical men having been thus honoured. The celebrated Professor von Langenbeck, who preceded Professor von Bergmann in the chair of surgery in Berlin University, was invested with this rank, but not until he had reached an advanced stage of his career, although in addition to his scientific eminence he had distinguished himself in two great wars. In THE LANCET of Oct. 13th, 1900, p. 1102, I mentioned that Professor Esmarch of Kiel had been created Wirklicher Geheimer Rath. He and Professor von Bergmann are the only two medical men at present in possession of this dignity.

### *Cancer and Malaria.*

Some months ago Professor Loeffler drew attention to the circumstance that carcinoma had become more prevalent since the decline of malaria in Europe, and, as mentioned in THE LANCET of Nov. 30th, 1901, p. 1541, he suggested that a collective investigation should be made for the purpose of ascertaining whether cancer was less frequent in malarial than in non-malarial countries. In an article published in the *Munchener Medicinische Wochenschrift* Professor Kruse of the Hygienic Institute of Bonn has compared the death-rates from cancer and malaria in different countries. He found that in Italy during the period 1887–1891 the death-rate from malaria was 5·81 per 10,000, but the death-rate from cancer was nearly the same as in Prussia and Austria where no death was caused by malaria during the period in question. It appears that cancer is more prevalent in the north of Italy than in the south, and conversely that malaria is more prevalent in the south than in the north, but on the whole he thinks that these differences are due to racial rather than to climatic or geographical causes.

Feb. 17th.

# Obituary.

## SAMUEL ROBERT LOVETT, L.R.C.P. EDIN., L.R.C.S. IREL., L.S.A. LOND.

BY the death of Samuel Robert Lovett the medical profession loses one of its oldest health officers. Mr. Lovett, who was born in 1833, was educated at King's College Hospital. His father was one of the parish medical officers of the parish of St. Giles-in-the-Fields and Mr. Lovett assisted him before as well as after he became qualified. From a notice in the February number of *Public Health*, a proof of which has been courteously supplied to us by the editor, we learn that in 1875 Mr. Lovett was appointed medical officer of health for the district of St. Giles-in-the-Fields and St. George, Bloomsbury. Some years later the Ville of Lincoln's Inn was also placed under his care and he held both appointments until the coming into force of the London Government Act, 1899, when he retired with the highest pension possible. Unfortunately, just at the time he was seized with an acute illness which left him in a very enfeebled condition. Mr. Lovett was instrumental in bringing about several radical clearances of slum property in St. Giles district, notably the Great Wild-street, Little Coram-street, and Shelton-street areas, which were dealt with under the Artizan and Labourers' Dwellings Act, 1875, in addition to which he reported nearly 200 houses under Part II. of the Housing of the Working Classes Act, and he was at all times ready to assist his colleagues with the benefit of his experience. Mr. Lovett's connexion with the Incorporated Society of Medical Officers of Health dates from 1875, and before long he was elected a member of the council and auditor of accounts. In 1880 he was elected honorary treasurer, which office he continued to hold, greatly to the advantage of the society, till 1894, when he was chosen president. After the International Congress of Hygiene and Demography in London in 1891 the society presented Mr. Lovett with a service of plate in recognition of his services as treasurer. It will be remembered that the society's journal, *Public Health*, was the official organ of the Congress, with a daily issue, under the editorship of the present president, Mr. A. Wynter Blyth, and a good deal of work fell on Mr. Lovett in connexion with the financial arrangements of the undertaking. A few months ago, in consequence of continued ill-health, Mr. Lovett resigned his fellowship of the society, and as a further mark of its appreciation of his services the society unanimously elected him an honorary fellow. At the request of the council Dr. E. C. Seaton attended the funeral at Brompton Cemetery on behalf of the society and placed a wreath on the coffin. Other floral tributes included those from the staff of the late St Giles Board of Works, from the Lodge of Fidelity (of which Mr. Lovett was a past master and for many years secretary), as well as from many private friends and official colleagues

## CECIL LATTER, M.A., M.D., B.C. CANTAB.

HIS many friends will learn with deep regret of the sudden death of Dr. Cecil Latter of Folkestone, which took place

Ireland and of enjoying all the advantages to be obtained from collegiate life This movement follows largely the suggested settlement of the Irish University problem made by Professor Mahaffy in his evidence before the Commission at its last sittings which were held in London

## PARIS.

(FROM OUR OWN CORRESPONDENT)

### *The Decay of Population in France*

THERE has been founded at Paris a league, with the title of "Ligue contre la Mortalite Infantile," for the study and active propaganda of methods calculated to combat in every way possible the excessive and preventable infantile mortality so prevalent in France The league will further in all ways private effort for amelioration in any district where statistics show that such effort is desirable It will also, with the aid of municipalities and of medical men, inquire into the causes of the excessive mortality which exists in certain districts and according to the results of these local inquiries will publish the best measures to be taken, and it will give hearty aid to municipalities or private benefactors who may wish to start refuges, creches dispensaries, "*gouttes de lait*," or other institutions for the distribution of sterilised milk or any similar institution In one word the league wishes to help forward any method or society having for its object to help poor mothers and children brought up by them, whether such children be brought up by their own mothers or by "minders" or in charitable institutions The league will also do its utmost to spread the light as far as regards infantile hygiene by collecting all information possible both from French and from foreign sources and by publishing pamphlets and leaflets on the subject Among those who have given their warm approbation to the scheme are Dr Budin, Professor at the Faculty, Member of the Academy of Medicine; Dr Fournier, Professor at the Faculty, Member of the Academy of Medicine, Dr Duclaux, Member of the Academy of Medicine, Director of the Pasteur Institute, Dr Josias, Member of the Academy of Medicine, physician to the Bretonneau Hospital, Dr Leon Labbé, Senator, Dr Theophile Roussel, Senator, Dr Grancher, Professor at the Faculty, Member of the Academy of Medicine, and Dr Variot, physician to the Hospital for Sick Children The president is Dr Th Roussel, the vice presidents are M Paul Strauss and M Pierre Budin, the secretaries are Dr Josias and Dr Variot, and the treasurer is Dr Henri de Rothschild In its turn the Government has just appointed an extra Parliamentary Commission to inquire into the best means of combating the decay of population Among the members of this commission are the following medical men Dr J Bertillon, Dr Borne, Dr Budin, Dr Dron, Dr Drouineau, Dr Emile Dubois, Dr Fumouze, Dr Gauthier, Dr Labbé Dr Lannelongue, Dr Letulle, Dr A J Martin, Dr Maurel, Dr Pinard, Dr Roy, Dr Richet, and Dr Variot

### *The Sealed Letter Archive at the Academy of Medicine*

The meeting of the Academy of Medicine on Feb 4th was held *in camerâ* and important alterations in the rules of the society were agreed upon The reasons for this change were as follows The Academy had become aware that certain persons abused their privileges and the weight which the name of the academy carries by bringing before it papers which were devoid of any scientific value and were, in fact, nothing but advertisements These were afterwards reproduced as serious works submitted to the Academy Up to the present, when anyone who is not a member of the Academy wished to read a paper before it he was obliged to get the paper revised by the secretary, but nothing but the title of the paper and the name of the author were reproduced in the Transactions of the Academy The same rule held good with regard to the correspondence addressed to the President and read at the end of the sitting However, this difficulty was surmounted in the following manner Anybody has a right to submit a communication as a sealed letter to be kept stored in the archives of the academy In this way, anyone engaged in research is assured of rights of priority, even though, as is often the case he does not wish to make public his researches until they are quite finished, which may not be for some time As soon as this happens he can demand that his sealed letter shall be opened and read before the Academy and it is finally printed in the Transactions In this way various charlatans have been able to obtain not only a reading but an official recognition of their lucubrations by the Academy. However, the Academy has now decided that no such reading or publication shall take place without the formal approbation of the committee of the Academy. This is a wise decision, but some means will have to be found of reconciling the new regulation with the approval *in posse* which the mere reception of the sealed letter would seem to imply

### *The Death of Doodica*

Doodica, one of the little girls making up the xiphopagous monster whose division by Dr Doyen I described to your readers in the last issue of THE LANCET, died on Sunday, Feb 16th The post mortem examination revealed complete union of the operation wound and there was no trace of hæmorrhage around the divided liver tissue The peritoneum was thickly studded with tubercles, and besides there was in the right iliac fossa an enormous peri cæcal abscess which had been set up by an appendicitis The appendix was gangrenous and there was intestinal perforation No surgical measures would have been of any avail in a condition of such widespread disease even if the condition had been diagnosed Radica, the other twin, continues to improve at the time of writing

(FROM OUR OWN CORRESPONDENT)

### *Accusations against Berlin Hospitals*

IN the German Parliament not long ago serious accusations were made against the Berlin hospitals on the occasion of a debate on the Budget The subject was introduced by Herr Antrick, a member of the Socialist party, who drew attention especially to matters connected with nursing He said that the male attendants of whom a large number were employed in the State and municipal hospitals, were ill-paid, over-worked and insufficiently fed The consequence was that changes were very frequent among them, for the majority of them looked upon nursing work only as a temporary occupation and resigned their situations whenever they could find other employment Male attendants were therefore not so much in request now as they formerly were, and had been replaced to some extent by female nurses belonging either to religious orders or to private associations These nurses it now appears, have their detractors, one of whom has recently published a pamphlet from which Herr Antrick quoted in the course of his speech In this work, the author of which has evidently been a male attendant, it is alleged that the moral standard of the nurses other than those belonging to the religious orders is not very high that they do not object to nursing male patients suffering from venereal complaints and other diseases of the generative organs, and that they have a liking for being present at operations on these organs Another of the charges is directed against the matrons, who, it is said, tyrannise over the nurses and sometimes set themselves in opposition to the medical staff Two cases are even mentioned in which matrons by means of various machinations had succeeded in bringing about the removal of the principal medical officers of hospitals. A hospital in Berlin is also referred to, where about 20 children became infected with gonorrhœa, the explanation of which was that they had been washed with one sponge and this sponge contained gonococci Another of the alleged grounds of complaint is that the chief medical officers have too many patients allotted to them, so many, in fact, that they are unable to do more than give attention to the so called interesting cases the remainder of the patients being left to the care of the assistant and junior medical officers (Volontärärzte) In order that the last sentence may be intelligible to English readers it must be explained that there are many points of difference between the hospital systems of England and Germany In all the great hospitals of Germany belonging either to the State or to municipalities the medical officers both the chief medical officer and the assistants, receive a fixed salary, which in Berlin amounts to 6000 marks (£300) for the chief physicians and surgeons apart from free house accommodation for themselves and their families The position which they hold is therefore not an honorary one, as in an English hospital, but they are

Hospital the same year and was a prizeman in physiology in May, 1851. In 1859 he joined the medical service of H.M. Indian Army and was attached to the 1st European Regiment of Madras Fusiliers (102nd Royal Dublin Fusiliers), his commission bearing date Feb. 10th. In 1861 he left India on sick leave, and from that year he practised at Mentone during the winter and spring, and from 1864 was nominated one of the Officiers de Santé in the Alpes Maritimes.

At Mentone Dr. Marriott was noted for his kindness and unaffected manners and the interest he took in his patients. He was a sincerely religious man and performed innumerable acts of kindness to the poorer classes of English who were obliged to reside at Mentone for their health. He was devoted to botany and years ago raised some funds for the first English church at Mentone by giving lectures on this favourite subject. He also made a valuable herbarium in the Alpes Maritimes and other parts of Europe. He married a daughter of the late Gerald FitzGerald, of the Queen's County. Ireland, and of St. James's-square, Bath, and leaves one son.

UNIVERSITY OF LONDON.—At the preliminary scientific examination held in January, the following candidates were successful:—

*Entire Examination.*

*First Division.*—Stanley James Annear Beale, London Hospital and University of New Zealand; Sheldon Francis Dudley, Merchant Taylors' School; Henry John Nightingale, St. Thomas's Hospital; and Alexander Morton Pollard, King's College and Alwyne Institution.

*Second Division.*—Josephine Eugenie Louise Griffiths, University College, Aberystwith; Charles Colgate Holman, Eastbourne College; Austin Threlfal Nankivell, Dulwich College and private study; Basil Thomas Parsons-Smith, University Tutorial College; Elsie Muriel Smith, London (Royal Free Hospital) School of Medicine for Women; John Heatly Spencer, Charing Cross Hospital and Alwyne Institution; and Ronald Ernest Todd, St. Thomas's Hospital.

*Chemistry and Experimental Physics.*

*Godfrey Frederick Ely Allison, Guy's Hospital and William Ellis Endowed School; *James Appleyard, University College and private study; *C. James Armstrong-Dash, St. Bartholomew's Hospital; *Charles Anthony Basker and *John Albert Bullbrook, Guy's Hospital; *Angel Camacho, Charing Cross Hospital and Alwyne Institution; Lawrence Croft, Yorkshire College and Bradford Municipal Technical College; *Wilfrid James Parsons Dicks, private tuition; Reginald Lionel Ernest Downer and *Archibald Thomas W. Forrester, St. Bartholomew's Hospital; *Henry Mellor Fort, Owens College; *Eric Henry Rhys Harries, London Hospital; *Charles Thomas Hawkins, University College, Cardiff; *Reginald Beaumont Heygate, Middlesex Hospital and Epsom College; *Reginald de Bracy M. Hopkins, University College, Bristol, and private study; *Charles Reginald Hoskyn, St. Bartholomew's Hospital; *Howell Tylford Howells, University College, Cardiff; *Edward Henry Hugo, Charing Cross Hospital and Epsom College; *Evan John Goronwy Jones, University College, Cardiff; *Ralph de Veil King, St. Mary's Hospital; *Alfred John Lee, University College and University Tutorial College; Harold Howard Leeson, University Tutorial College; *Ethel Mary Lomas, London (Royal Free Hospital) School of Medicine for Women; Clement Lovell, University Tutorial College and private study; *Philip Janvrin Marett, Birkbeck Institution; *E. M. Spencer Mecredy, Yorkshire College and private study; Howard Edward Hall Mitchell, Guy's Hospital; A. Wornum Mongredien, University Tutorial College and Birkbeck Institution; *John Griffiths Morgan, London Hospital; Humphrey Nockolds, Hartley College, Southampton; *Charles Louis Claude Owen, private study; *Joseph Owen, London Hospital; *Owen Brynog Parry, Birkbeck Institution and University Tutorial College; Walter Patey, Dulwich College; Arthur John Scott Pinchin, South Western Polytechnic and private study; *Edward John Price, University College, Aberystwith; *Eliza Macdonald Smith, London (Royal Free Hospital) School of Medicine for Women and Alwyne Institution; *Nora Frances Smith, London (Royal Free Hospital) School of Medicine for Women; Ethelbert William Squire, St. Mary's Hospital; William Francis Sutcliffe, St. Thomas's Hospital; Harold Thwaite, Birmingham University and private tuition; *Thomas Williams Wade, University College, Cardiff; *Norman Hamilton Walker, St. Bartholomew's Hospital; Herbert Inman Welsh, St. Paul's School and private tuition; *Edgar Wharton, Owens College; *Joseph William James Willcox, University College, Bristol; and Hugh Owen Williams, University College, Cardiff.

*Biology.*

*Arnold Alcock, Owens College; Frederick Alfred Barter, London Hospital; Harold Henry Blake, University Tutorial College and private study; *Henry Joseph Cates, University Tutorial College and private study; *Bertram Walter Cherrett, Hartley College, Southampton; Philip Crawford Conran, St. Paul's School and University Tutorial College; *Samuel Wilfrid Daw and A. Ffolliott William Denning, Guy's Hospital; Thomas Evans, Univerity College, Aberystwith, and University Tutorial College; Rupert Farrant, Epsom College and private study; *Margaret Fisher, London (Royal Free Hospital) School of Medicine for Women; *Arthur Leslie Foster, Guy's Hospital; *Sidney Frank Fouracre, Charing Cross Hospital and Alwyne Institution; *Henry Leatham Grabham, St. Thomas's Hospital and Bedford Grammar School; *Hendrik Houwink, Birkbeck Institution; *Harold Emlyn Jones, London Hospital; Roger Percival Jones, University College, Cardiff; *Claude Herbert Marshall, Guy's Hospital and Dulwich College; M. Herschel E. R. Montesole and *Charles Max Page, St. Thomas's Hospital; *Arthur Haig Pollard, London Hospital; *Edgar Nelson Ramsbottom, Owens College; *Russell John Reynolds, Alwyne Institution and private study; *Arthur Herbert Rich, University Tutorial College; Claude Mallinson Rigby, Dulwich College; *Cecil Frederick Robertson, Middlesex Hospital and private tuition; *Arthur Frederick Sanderson, St. Thomas's Hospital; Frank Standish, London Hospital; Kenneth Henry Stokes, University Tutorial College; *Sydney Arthur Tucker, St. Bartholomew's Hospital; *Harold Arthur Whitcombe, Birmingham University and private study; *Cyril Underwood Whitney, Westminster Hospital; and *Arthur Zorab, Guy's Hospital.

* These candidates have already passed a part of the examination.

N.B.—The foregoing list, published for the convenience of candidates, is provisional only, and is not final until the reports of the examiners shall have been confirmed by the Senate.

UNIVERSITY OF CAMBRIDGE.—At the congregation held on Feb. 13th the following medical degrees were conferred:—

*Doctor of Medicine.*—L. T. R. Hutchinson, Trinity; G. C. Taylor Christ's.

*Bachelor of Medicine and Bachelor of Surgery.*—D. J. Morgan, St. John's; J. G. Cooke, Sidney Sussex.

VACCINATION IN WORKHOUSES.—At the meeting of the St. Austell (Cornwall) Board of Guardians held on Feb. 8th it was decided that every tramp coming into the workhouse should be vaccinated.—The Kingsbridge (Devon) Board of Guardians at its meeting on Feb. 8th decided that all the children over seven years of age in the workhouse, and such of the adults as wished it, should be revaccinated.

BRITISH MEDICAL BENEVOLENT FUND.—The annual general meeting of subscribers to the British Medical Benevolent Fund was held on Feb. 18th, Sir William H. Broadbent, Bart., K.C.V.O., the President, being in the chair. The report of the committee and the treasurer's financial statement for the past year were presented and adopted. In the grant department subscriptions amounting to £1110 9*s.* 2*d.* and donations amounting to £369 8*s.* 3*d.* had been received, and £1614 1*s.* had been distributed to 161 applicants in sums varying from £5 to £20. In the annuity department the income from capital had been £2419 8*s.* 5*d.*, of which £2288 6*s.* 8*d.* had been paid to pensioners of the age of 60 years and upwards, the number being now 114. The working expenses of the fund had been, as for so many years past, less than 5 per cent. and the accounts had been subjected to the usual strict investigation by a chartered accountant. The report stated that it was impossible to give adequate help, even to the most distressing cases, on account of the restricted means at the disposal of the committee, and it expressed a hope that every subscriber would endeavour to interest others in the work of the charity. Hearty votes of thanks were passed to the President and other officers, who were unanimously re-elected and the meeting concluded with a warm acknowledgment of the support always given to the charity by the medical press.

THE CHANGES IN CHEESE.—At a recent meeting of the Society of Chemical Industry Dr. W. F. Sutherst, F.C.S., Professor of Agricultural Science at the Cheshire Agricultural College, Chelford, read a paper on the "Ripening" of Cheese. He said that the final explanation of the process was still wanting, but two agencies—namely, microbes and the ferments which broke up the complicated bodies in the curd into simpler ones—were the chief causes. The microbic action was most varied, and to it the peculiar taste of different cheeses was due. But the moulds and fungi were capable, apart from bacteria, of ripening cheese. It might be possible to make any kind of cheese by causing the particular microbe of that variety to be dominant in the curd. The very technical chemical analysis of cheese was explained and the variations in the chemical groups that go to make up a cheese in its different stages were traced. As the chairman, Dr. Grossman, said, it is well known that cheese-making has been a very empirical proceeding. Mr. D. B. Hewitt, a member of the Cheshire County Council, complimented Dr. Sutherst on his paper and said that he remembered being asked by a prominent agriculturist why a cheese lost colour in one part and not in another, and also what it was that gave it its particular flavour, and why in Cheshire the old long-keeping cheese on the evening of Jan 29th under circumstances of singular sadness He was staying with a medical friend in London and while hurrying across Hyde park to be in time for dinner was seized with heart failure and died during his conveyance to St George's Hospital To those who had seen much of him of late this sudden end was not wholly unexpected as signs of heart weakness had shown themselves previously and the general condition had been lowered by insomnia He may be said never fully to have recovered from a very severe attack of complicated scarlet fever contracted at the end of his term of service as assistant medical officer at the Western Fever Hospital in 1893

Cecil Latter, the son of the late Rev Arthur S Latter, was born in 1866 In 1884 he left Charterhouse with a science scholarship and entered at Pembroke College, Cambridge, where he graduated in the natural science tripos in 1887 Mental abilities of a marked order enabled him to grasp and to retain very easily the details of an education in natural science, but science in itself did not really attract him His real interests were always human and as quite a young man he exhibited in a remarkable degree the power of insight into character , he was acutely critical but nearly always in the sense of seeing good qualities where others missed them In 1888 he entered at St Thomas's Hospital, where, becoming at once intensely interested in the human side of medicine, he gave his very able mind for the first time to the serious study of its science and art, and as a consequence scored a brilliant record there taking the Mead medal in 1891 and earning the esteem of the staff and of his fellow students He held the various resident posts at St Thomas's Hospital and then acted as assistant medical officer at the Gore Farm Convalescent Hospital and at the Western Fever Hospital contracting at the latter the illness which was permanently to weaken him Feeling strongly that the most complete and satisfactory function of medicine was that exercised by the family physician, Dr Latter elected to enter at once upon general practice and in 1893, after convalescence from the fever, he settled at Folkestone In the same year he married the daughter of Mr William Beechey, and for this lady and her little son the most profound sympathy is now expressed by many friends both in and outside the profession At Folkestone Dr Latter soon began to acquire the work and to occupy the position to which he was entitled as a medical man unusually well equipped in his profession and possessed besides of a mind both original and highly cultivated He took an active share in the work of the Folkestone Medical Society in its early days proving an invaluable honorary secretary in 1894 and 1895 and a frequent contributor to its debates He was elected to the staff of the Folkestone Hospital as well as to that of the St Andrew's Convalescent Home He always realised very keenly that members of our profession owed special public duties to the community, and a few years since he read a paper before the British Balneological and Climatological Society, urging his views on the subject He put his doctrine into practice by getting himself elected in 1899 to the town council, on which body he proved himself an active citizen particularly where public sanitation was concerned The same sense of public duty made him devote a great deal of time and energy to lecturing upon first aid and ambulance work, especially among the fishermen who repaid him with affectionate gratitude It seems probable that his enthusiasm for municipal work put upon his constitution a strain greater than it could bear, for he never permitted it to interfere with the exactions of a large and increasing practice or with his work at the hospital His untimely death has called forth expressions of deep personal regret from members of every class in Folkestone where so many have lost in him not merely a skilful medical man but a sincere friend

---

## D'ARCY BAINBRIDGE CARTER M R C S Eng , L R C P Edin

On Feb 8th there were laid to rest the mortal remains of D'Arcy Bainbridge Carter of Shipley who died from heart failure and pneumonia The deceased was educated at Leeds Grammar School and at the Old Leeds School of Medicine He qualified in 1881 As house surgeon to the General Infirmary at Leeds and afterwards resident medical officer to the Clayton Hospital Wakefield he built up a sound foundation of professional knowledge and in 1884 he entered into partnership with Mr W H Ellis of Shipley The many public appointments which he subsequently held, including as they did the post of surgeon to the Sir Titus Salt Hospital, Saltaire, surgeon to the Great Northern and Midland Railways and to the Eastern Division of the West Riding Constabulary, and medical officer to the Woodhouse Grove School are proofs of the value placed upon his skill and judgment Mr Carter also trained members of the local ambulance association for service in South Africa In short, there was no local movement in which he did not heartily cooperate for the benefit of his fellow townsmen

Although the weather of Feb 8th was of the most inclement description, snow falling heavily throughout the whole day, it did not prevent the people of Shipley from assembling in hundreds to pay a last mark of respect to the man who for the past 18 years had been alike their medical attendant and their friend No one who witnessed the funeral procession could fail to have been impressed with the sincerity of the vast gathering which included men and women of all ranks In conjunction with his partner, Mr Ellis Mr Carter worked hard in the carrying out of an extensive practice but devoted his leisure entirely to public work Mr Carter leaves a widow and two daughters , he died at the early age of 42 years He was a type of man too rarely met with—one who gave his best for others and who thought of himself last

---

## WILLIAM CHARLES HILLS, M D Aberd , M R C S Eng , L S A

Dr W C Hills was the second son of Mr Monson Hills the elder, resident apothecary and cupper of Guy's Hospital, and was born within its precincts in February, 1828 He received his early education at the Merchant Taylors' School and his medical training at Guy's Hospital, where he was intimately known to Sir W W Gull Mr Bryant, Sir Samuel Wilks, and many others After qualifying as M R C S , L S A , in 1850 he was appointed house surgeon at the Surrey Dispensary, and subsequently in 1854 was elected assistant medical officer at the Kent Asylum at Barming Heath, near Maidstone under Dr James Huxley, who is still living, the brother of the late Professor Huxley In 1859 he graduated as M D Aberd and in 1861 he was promoted to the medical superintendency of the Norfolk County Asylum at Thorpe which post he filled with great ability and tact until January, 1887, when he retired on a well earned pension of £600 a year The remaining 15 years of his life were usefully employed as an alienist consultant in the county with which he had been so long associated and in gratuitous medical work amongst the poor of his district, by whom he was beloved Death came to him suddenly from cardiac failure shortly after retiring to bed at his house in The Chantry, Norwich, on Jan 18th last, and on the 22nd he was laid to rest in the picturesque churchyard of Postwick, near Thorpe beside his second wife and only son who had predeceased him He leaves one daughter, Mrs Aubrey A Blake to mourn her loss The funeral was largely attended by medical friends including Mr William Cadge, Mr Charles Williams Mr Charles Muriel, Mr Thomas H Morse and his old friend Dr Ernest W White, with whom in recent years he had generally spent a few weeks each summer at the City of London Asylum for to the last he was eager to keep himself abreast of the times in the treatment of mental diseases

---

## PETER WILLIAM MARRIOTT, M D St And , M R C P Lond , M R C S Eng F L S

We regret to record the death on Feb 1st of Dr Marriott of Mentone He was born on June 30th 1831, and was the second son of the Rev Harvey Marriott, vicar of Wellington, Somerset and 40 years rector of Claverton Bath His grandfather, William Marriott, H E I C S , Governor of the province of Burdwan (then of some importance) near Calcutta, was brother of Randolph Marriott of Avenbury, and son of the Rev Randolph Marriott, D D , of the Leases, Bedale, Yorks, rector of Darfield, by his wife, Lady Diana, daughter of the fourth Earl of Denbigh, Count of Hapsburg, &c He was educated at Edinburgh Academy, where in July, 1846 in the fifth class he won the prizes for the best sapphics, the best Latin hexameters and pentameters and one for scholarship He worked in the Bath United Hospital in 1849 and in 1850 matriculated at the London University He entered the college of St. Bartholomew's children 413 were successfully vaccinated, 24 conscientious objection certificates were granted, and 62 children died unvaccinated, leaving 98 unaccounted for, the majority of whom had certificates of postponement.—The vaccination returns for Bristol show that during the first six months of 1901 there were 9089 births registered. Of these children 5216 were successfully vaccinated, 222 were granted certificates of exemption on the ground of conscientious objection, and 996 died unvaccinated.

# Parliamentary Intelligence.

## HOUSE OF LORDS.

### MONDAY, FEB. 17TH.

### *Proposal to Abolish the Conscientious Objector.*

Lord NEWTON moved the second reading of a Bill to amend the Vaccination Act of 1898 by repealing the conscientious objector clause. His lordship said that he did not think that there was any sympathy in any part of the House with the person known as the "conscientious objector." The Lord Chancellor had caused all the officials at the law courts under his control to be vaccinated, and he was not aware that his lordship had made any exception in favour of the conscientious objector or anybody else. Nobody liked him and many hated him. Why not, therefore, take this opportunity of getting rid of him? When the Bill of 1893 was introduced there was no mention whatever of the conscientious objector; it was only after the sacrifice of Mr. Chaplin, then President of the Local Government Board, that the clause he now wished to see repealed appeared in the measure. His contention was that the clause had made easier the path of the anti-vaccinationist to the danger of the community at large, that it was mischievous and retrograde, and that as a matter of common-sense Parliament ought to repeal it.

Viscount GALWAY, supporting the Bill, said that in his opinion the clause constituted a danger to the community.

Lord KENYON pointed out that the whole Act was in the nature of an experiment and that in the ordinary course of things it would expire in 1903, when it would be necessary to review the whole situation. In these circumstances he thought that it would be unwise to pass this Bill.

Lord PIRBRIGHT expressed the view that the logical course for their lordships would be to abolish the conscientious objector at once.

Lord BALFOUR of BURLEIGH said that the issue raised in this matter was simply whether the conscientious objector clause should be allowed to expire with the Act itself at the end of 1903, or be brought to an end on Jan. 1st, 1903, by this Bill. Personally he was a believer in vaccination, as he believed that every member of the Government was, and he had testified to that belief by himself submitting to revaccination. He was responsible for vaccination in Scotland, where the conscientious objector was not known and where they got on very well without him. They might say that people ought to be vaccinated, and proceed if they chose to put them in prison for not having their children vaccinated; but in a country governed as this country was it was impossible to enforce a law if a large proportion of the people had made up their minds that the law was wrong. There was a state of rebellion against the law, arising partly from the carelessness with which vaccination had been administered and partly to a well-planned agitation. Two or three things were done. The vaccination officers had been instructed and empowered to administer vaccination on different lines; the obligation to take children to vaccination stations was, if not abolished, largely modified; the public vaccinators were empowered, and paid, to attend at the house, and the practice of arm to-arm vaccination was got rid of and purer lymph supplied. It was hoped that by the operation of these and other causes the prejudice against vaccination would die away. A period of grace was believed to be necessary during which these prejudices could be combated and popular opinion changed He was authorised by the President of the Local Government Board to say that, so far as his information went, the administration of vaccination under the law as it now stood was a great deal more successful than it had been before. He (Lord Balfour) did not go so far as to say that this was owing entirely to the liberty given to the conscientious objector. It was enough to say that the Act of 1898 had been highly successful, that it was tending to be more successful, and that he should look with great concern on any decision of that House which upset the compromise of 1898 a year before its natural time, as likely to encourage prejudice and agitation rather than to allay them. He did not think it possible to make out that the present epidemic was in any way connected with the legislation of 1898, because those who took advantage of the conscientious objector clause could not have been more than 14 years of age in 1893, and of those who had been born since only an average of some 32,000 or 33,000 a year had availed themselves of this provision. To make out that the present epidemic was connected with the legislation of 1898 it would be necessary to prove that only those, or mainly those, who had taken advantage of the clause were now the victims of the epidemic. Vaccination in London was on the whole better enforced than in any other part of England. People who were against vaccination might make an argumentative use of that admission and ask why, if London were better protected, it had this epidemic. That was due to a variety of causes which, if it were expedient, it might be necessary to examine. But there was not the slightest evidence to prove that either this epidemic or any other occurring since the Act of 1898 was passed was due to the legislation of that year.

The LORD CHANCELLOR said that he was unable to vote for this Bill, although if they were discussing the subject for the first time he did not say that he should disagree with the mover of the second reading. He had no power to make an order that all people employed at the Law Courts should be vaccinated. He had, however, intimated, and he proposed to act upon the intimation, that if they were not they would no longer be admitted. He hoped their lordships would not now interfere with the compromise made in 1898 and depart from that kind of understanding without which it would be very difficult to conduct public business in this country.

Earl SPENCER spoke in favour of the experiment being left undisturbed in the hope that the public feeling against vaccination might be allayed.

On a division being taken the Bill was thrown out by 52 to 32 votes.

### TUESDAY, FEB. 18TH.

### *Shops (Early Closing) Bill.*

The result of a second reading debate on this Bill was the rejection of the measure by 57 against 26 votes. The Bill was introduced by Lord AVEBURY, long known in the House of Commons in connexion with this subject as Sir John Lubbock. It proposed to give to local authorities on the application of two-thirds of the shopkeepers in their district the power of enforcing certain regulations as to hours of closing and half-holidays.

## HOUSE OF COMMONS.

### THURSDAY, FEB. 13TH.

### *Royal Commission on Tuberculosis.*

Sir WALTER FOSTER asked the President of the Local Government Board if he could state the localities in which the farms were situated at which the experiments of the Royal Commission on Tuberculosis would be carried out and the condition on which these farms had been obtained and the necessary laboratories and buildings erected.—Mr. LONG replied: The two farms referred to are situated at Stansted, in Essex. They belong to Sir James Blyth who has most generously placed them at the disposal of the Royal Commission for experimental work free of charge. The Government have expressed to Sir James Blyth their warm appreciation of his act, which will greatly facilitate the labours of the Commission. Arrangements have been made for the occupation of the farms for a period of three years, though it is hoped that the inquiry will be completed within a shorter period. The Commissioners have caused to be erected on the farms the laboratories and other buildings necessary for their experiments.

### *The Supply of Lymph.*

A question on this subject was addressed by Mr. BULL to Mr. Long who referred the hon. Member to previous answers which he had given and said that as at present advised he did not propose to ask for power to control the lymph supplied from outside sources.—Mr. THOMAS BAYLEY asked the President of the Local Government Board whether his attention had been drawn to the use of small-pox virus passed through pustules on monkeys as a source of vaccine by Dr. S. Monckton Copeman, medical inspector, Local Government Board, who stated that a considerable number of children had been vaccinated with vaccine thus obtained; and whether the Local Government Board had given its medical inspector leave to vaccinate children with vaccine of such a nature.—Mr. LONG replied that Dr. Copeman had informed him that he had made experiments of the kind referred to, but the Local Government Board had not given him permission to vaccinate children with lymph yielded by the monkey, and he (Mr. Long) understood that he had not done so. In all cases vaccinations had been performed with lymph derived direct from the calf.

### FRIDAY, FEB. 14TH.

### *The Superannuation Question in Ireland.*

Mr. CAREW asked the Attorney-General for Ireland whether all the officers, including the doctors, the apothecaries (who in most cases were also the treasurers), matrons, nurses, and porters to the different county infirmaries in Ireland, who on the passing of the Local Government Act of 1898 were transferred to the county councils, were entitled to pensions under the existing regulations.—The ATTORNEY-GENERAL (Mr. ATKINSON) replied that officers of county infirmaries were not officers of the Grand Juries and were not transferred to the county councils by the Local Government Act, 1898. The rights of existing officers of these institutions were preserved by section 15, sub-section 8, of the Act, but apparently no right to pension on retirement existed prior to the Act, and no such right was conferred by it.

### *The Use of Preservatives and Colouring Matters in Food.*

In reply to a question addressed to him by Mr. JOYCE asking him whether he had taken any steps to carry out the recommendations of the Departmental Committee on this subject Mr. LONG said that legislation would be necessary to give effect to these recommendations, and he had not yet arrived at a decision as to the course to be taken.

### *Typhoid Fever Among the Troops in South Africa.*

Sir WALTER FOSTER asked the Secretary of State for War if he could state the number of cases of typhoid fever and the number of deaths from that disease which had occurred among the troops serving in South Africa since May, 1901, giving, if possible, the numbers of cases and deaths for each month.—Lord STANLEY replied: The figures are as follows:—

| | Admissions. | Deaths. |
|---|---|---|
| June | 885 | 170 |
| July | 324 | 68 |
| August | 328 | 73 |
| September | 257 | 47 |
| October | 451 | 43 |
| November | 1091 | 160 |
| | 3336 | 561 |

### *The Royal Army Medical Corps.*

Sir WALTER FOSTER asked the Secretary of State for War whether he could state how many non-commissioned officers and men of the Royal Army Medical Corps had been sent from England to South Africa during the last seven months and how many of these had had actual training in hospitals in nursing the sick.—Lord STANLEY replied: Since July 1st, 1901, 1160 non-commissioned officers and men of the Royal Army Medical Corps have embarked for South Africa. Of these, 626 were enlisted in the usual way and had had actual training in military hospitals in nursing the sick. The remainder were enlisted under a special Army Order of March 11th, 1901, engaging men who had been trained in civil life. These all had good certificates of proficiency in was now very little made It seems likely that such researches as Dr. Sutherst's may introduce something like certainty into cheese-making, greatly to the advantage of the makers and the community at large.

WALTON CONVALESCENT HOME, CLEVEDON.—The annual report states that during 1901 there were 479 patients admitted, an increase of six on the previous year. The financial statement shows a balance in hand of £29.

SOCIETY OF APOTHECARIES OF LONDON.—The Gillson Scholarship in Pathology, 1902, has been awarded to Dr. Herbert Stanley French, medical registrar at Guy's Hospital.

VICTORIA HOSPITAL, SWINDON —The fourteenth annual meeting of the subscribers of this institution was held on Feb. 8th. The medical report stated that 262 in-patients had been admitted during 1901, against 230 in 1900. The financial statement showed that the total income amounted to £765 and that there was a favourable balance of £178

MANUFACTURE OF CHLORATE OF POTASH.—It may be remembered that in connexion with the explosion at the Kurtz Chemical Works at St. Helens in May, 1899, it was asked if chlorate of potash was "explosive by itself." The recent experiments of Dr Dupré prove that under some circumstances, as when a bead of chlorate is suddenly brought to a high temperature by passing an electric current through a loop of platinum wire in which the bead is held, an explosion results Manufacturers seem unwilling to believe this.

A DISPUTED DIAGNOSIS.—The medical attendant of a man who died at Penydarren, South Wales, on Feb 3rd was prepared to certify that the cause of death was bronchitis and fatty heart, but the son of the deceased disputed the diagnosis and refused to allow a post-mortem examination to be made. The medical man therefore refused to give a certificate and on Feb 7th an inquest was held at which he again stated that the death was due to bronchitis and fatty heart, and the jury at once returned a verdict in accordance with that evidence. The coroner characterised the conduct of the son as utterly absurd.

BEQUESTS AND DONATIONS TO HOSPITALS.—Mr. and Mrs. John Stell of Keighley have given £500 to the new hospital at Keighley. The committee requires about £9000 to complete and equip the new premises.—Under the will of Mrs. Constance Trousdell of Byblox, Doneraile, county Cork, £50 are bequeathed to the City of Dublin Hospital —In connexion with the provision of a nurses' home at the North Staffordshire Infirmary, the King, who laid the foundation-stone of the infirmary in 1866, has forwarded £105 —Under the will of Mr. A. J. Dettmar the committee of the Hospital for Epilepsy and Paralysis and other Diseases of the Nervous System, Regent's-park, London, has received the sum of £9367 13*s.* 4*d.* for the new hospital now being built at Maida-vale

MEMORIAL TO THE LATE JAMES PRESCOTT JOULE.—The services of the late Dr. Joule to science attracted but scant public recognition during his life and his name has not received any worthy memorial. Now, however, it is proposed that Sale, a suburb of Manchester, where Dr. Joule lived a retired life, shall do itself honour by removing that reproach. Sir William H. Bailey has offered to present to the Sale District Council an automatic recording meteorological public clock at a cost of about £250, and Mr Frank Armstrong has offered a set of meteorological instruments, provided that they shall be suitably housed in the interests of the public. The district council is quite willing that a building shall be placed in the public park, and designs have been prepared for a tower to be called the "Joule Memorial Tower." It is to be a square building 40 or 50 feet high, with three clock dials and a dial to indicate the direction of the wind. The meteorological instruments will be in a room in the base of the building, while a tablet will be fixed outside, on which there will be a medallion portrait and a short record of Dr. Joule's work. The cost of the tower will be about £1000, which the district council would have provided had its funds been applicable for such a purpose. A committee has been formed to raise subscriptions, and it is believed that the object will appeal not only to those locally interested but to scientific men over a wider area. It is hoped that, apart from its being a memorial of Dr. Joule, it will receive official approval as a meteorological station. Mr. Charles E Lees is chairman of the executive committee of the fund and Mr. J. Walter Robson is the honorary secretary.

NOTIFICATION OF CHICKEN-POX.—At the meeting of the Exeter City Council held on Feb. 12th it was decided that chicken-pox should be included among the diseases to be notifiable under the Infectious Diseases Notification Act.

AT the meeting of the Plymouth Borough Council held on Feb 13th Dr. J. Rolston and Mr. G. A. Rae, L.R.C.P., L.R.C.S Edin., were elected members of the Plymouth Port Sanitary Authority.

SOUTHERN DISPENSARY, BATH.—The annual meeting of the subscribers to this institution was held on Feb. 4th under the presidency of General Jervois The medical report stated that 976 patients had been treated during 1901, being an increase on the previous year. The financial statement showed a favourable balance of £91.

GRANT FOR SUCCESSFUL VACCINATION.—Mr. Alfred G. Hebblethwaite, M.R.C.S. Eng., L.R.C.P. Lond., has received from the Local Government Board a gratuity for successful vaccination in the Keighley district, of which he is public vaccinator. This is very gratifying, seeing that the district is an anti-vaccinationist hotbed.

HEALTH OF BARNSTAPLE.—The medical officer of health of Barnstaple (Mr. J Harper), in his annual report for 1901, states that the population of that town is estimated at 17,962 389 births were registered during the year, equal to a rate of 22 04 per 1000 220 deaths occurred, corresponding to a rate of 12 43 per 1000.

A JUDGE ON VACCINATION.—At the opening of the Gloucestershire Winter Assizes, held at Gloucester on Feb 11th, Mr Justice Phillimore alluded to the late epidemic of small-pox in that city when the assizes were transferred to Cheltenham. He said that he was glad to hear that the lesson of the epidemic had not been lost on the city and that the protection afforded by vaccination was now recognised by the inhabitants

PRESENTATION TO A MEDICAL PRACTITIONER.—At an entertainment given at the Oddfellows' Hall, Plymouth, on Feb 12th, in connexion with the Great Western Railway Millbay Division of St. John Ambulance Brigade, Superintendent A. Ilott, on behalf of the members of the division, presented Mr. Henry Woolmington Webber, M.D., M.S., L.R.C.P. Lond., M.R.C.S. Eng., with a silver fruit-dish in recognition of his services as honorary lecturer.

THE ROYAL INSTITUTION.—Magic Squares formed the subject of the Friday evening discourse delivered at the Royal Institution on Feb. 14th by Major Percy A. Macmahon, Royal Artillery. A magic square is one divided like a chessboard into any number of equal squares, in each of which is placed one of a series of consecutive numbers from 1 up to the square of the number of cells in a side, in such a manner that the sum of those in each horizontal row, each vertical column, and each of the two diagonals is constant Major Macmahon said that these squares had been known from a remote period; they were at one time supposed to possess occult qualities and had been worn as amulets. Euler and several other eminent mathematicians of later date had investigated their properties, as it was found that they served to illustrate some points in the theory of numbers and the theory of groups A brief reference was also made to Nasik squares and Nasik cubes Several Nasik cubes are shown on the upper floor of the western gallery of the Museum in South Kensington

VACCINATION RETURNS.—At the meeting of the Exeter Board of Guardians held on Feb 11th the vaccination returns for 1900 were presented, which showed that during that year 831 births were registered; of these children 640 were successfully vaccinated, 30 were exempted on the ground of conscientious objection, 93 died unvaccinated, seven were medically postponed, 23 changed their address, and 38 were otherwise unaccounted for. During the first six months of 1901 there were 422 births registered. Of these children 288 were successfully vaccinated, 12 were exempted on the ground of conscientious objection, and 63 died unvaccinated.—The vaccination returns for Penzance Union for the first six months of 1901, which have just been issued, show that 597 births were registered. Of these

# Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

**Allport, R. H.**, M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Acts for the Loughton District of Essex.

**Berry, H. Poole**, M.B. Lond., has been re-appointed Medical Officer of Health to the Grantham Corporation.

**Brown, Henry Reynolds**, M.B., M.S.Edin., has been appointed Medical Officer of Health to the Malden Urban District Council and Port Sanitary Authority, Essex.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeon, under the Factory Acts, at Heckington, *in the county of Lincoln, and* at Luton in the county of Bedford.

# Births, Marriages, and Deaths.

## BIRTHS.

**Burrell.**—On Feb. 17th, at Arlarie, Kew, the wife of Lionel Cottingham Burrell, M.A., M.B., B.C. Cantab., of a daughter.

**Crone.**—On Feb 4th, at Kensal Lodge, Kensal-rise, N.W., the wife of J. S. Crone, L.K.Q.C.P. Irel., L.S.A., J.P., Chairman Willesden District Council, of a son.

**Fisher.**—On Feb. 10th, at Sittingbourne, the wife of H. Holdrich Fisher, M.D. Lond., of a son.

**Hinds.**—On Feb. 13th, at Bexley House, Crayford, Kent, the wife of Thomas W. Hinds, M.D. Lond., of a son.

**Powell.**—On Feb. 15th, at Calverton Lodge, Stony Stratford, the wife of Cecil Powell, M.A., M.B. Cantab., of a daughter.

**Robinson.**—On Feb. 14th, at Gladwins, Limpsfield, the wife of Charles Allen Robinson, B.A., M.B., B.C. Cantab., of a son.

**Stewart.**—On Feb. 16th, at Walton House, Lordship-lane, S.E., the wife of H. M. Stewart, M.A., M.D. Cantab., of a son.

**Waring.**—On Feb. 14th, at Wimpole-street, W., the wife of H. J. Waring, M.S., M.B. Lond., F.R.C.S., of a son.

**Wharry.**—On Feb. 12th, at Park-street, Park-lane, the wife of Henry Gordon Wharry, M.R.C.S., of a son.

## DEATHS.

**Carter.**—February 5th, at Victoria Park, Shipley, *from acute pneumonia*, aged 42 years, D'Arcy Bainbridge Carter, M.R.C.S. Eng.

**Toller.**—On the 19th inst., to the great distress of his parents, and deeply lamented by his *friends*, at his residence, Cairo, Egypt, Seymour Graves Toller, M.D., M.R.C.P. Lond., aged 35, late Physician to Kasr-el-Aini Hospital, Caire, and late Assistant Physician to St. Thomas's Hospital, London. Friends will kindly accept this, the only intimation.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

first aid, ambulance drill, &c., but it is not possible to say exactly what actual nursing experience they had On arrival in South Africa the drafts are detailed by the principal medical officers according to their qualifications

### *The Enforcement of Vaccination*

Colonel **STOPFORD SACKVILLE** asked the President of the Local Government Board whether he was aware that a recent vacancy in the office of the vaccination officer in the Wellingborough district lasted from Oct 18th 1901, to Jan 30th, 1902, what was the reason for the delay in approving of the appointment made by the guardians, was any person appointed to act temporarily during the vacancy, and had he any information to show whether the vaccination laws were now effectually enforced within the limits of the Wellingborough Kettering and Thrapston unions —Mr **LONG** replied: In the case of Thrapston I understand that the vaccination officer is performing his duties satisfactorily and that prosecutions in cases of default are taking place I regret however to say that the information in my possession shows that the vaccination laws are not being effectually enforced in the other two unions to which my hon and gallant friend refers, and I am considering what steps should be taken in these and similar cases With regard to Wellingborough, in consequence of a report which I received from one of my medical inspectors I caused letters to be addressed to the vaccination officers of that union calling attention to the unsatisfactory way in which they were performing their duties and stating that they would not be allowed to retain office unless they were prepared to carry out their duties in accordance with the Vaccination Acts As a result one of the vaccination officers resigned The guardians appointed another person in his place in October last, but in view of the unsatisfactory replies received from the other two vaccination officers I felt much difficulty as to sanctioning the new appointment Sanction was eventually given last month in the case of this officer I have felt it necessary to call on the other vaccination officers to resign

### MONDAY, FEB 17TH

### *Vaccination and the Conscientious Objector*

Mr **LONG**, in reply to a question addressed to him by Mr **CHAPLIN** said that the Parliamentary return already issued gave the number of successful primary vaccinations for 1898 as 600 314 and for 1899 as 669 349 According to returns which he had since received the number for 1900 was 677 655 He had not at present received returns from all the unions for 1901 The number of certificates of conscientious objection received by vaccination officers were as follows: in 1898 203 413, in 1899, 32 341, in 1900, 39 839, and in the first six months of 1901, 19 252

### *The London Water Question*

Sir **SAMUEL SCOTT** asked the President of the Local Government Board whether he was prepared to insert in the London Water Bill a clause protecting the consumers of water in the area of the metropolis supplied by the Middlesex Water Company from the loss of the discount on their water rates to which by law they were now entitled —Mr **LONG** replied Under Clause 35 of the Bill the scale of water charges enforceable by the West Middlesex Company will continue in force until repealed altered or superseded The powers of the Water Board in this matter will be precisely similar to those of the company at the present time and I do not propose to insert any special provision in the Bill on the subject I do not express any opinion as to the legal right of consumers, but no such right which *now exists would be taken* away by the Bill

### *The Adulteration of Milk and Butter*

General **LAURIE** asked the President of the Local Government Board whether his attention had been called to the report of the public analyst for the borough of Paddington for the quarter ending June 24th, 1901 in which it was stated that, on a conviction for adulteration of milk by adding 22 per cent of water the magistrate inflicted a fine of 5*s*, and, in view of other similar prosecutions by local authorities for adulteration of milk and butter which had either failed in consequence of the terms of the contract or other such reasons or had resulted in either only the imposition of costs or modified fines whether he could, by legislation or by other means enable the local authorities to enforce the law against adulteration especially of those articles in constant demand among the humbler classes —Mr **LONG** replied: I have not yet received the report referred to in the question I have no authority to intervene in the manner suggested nor does it appear to me that I can undertake to provide legislation on the subject I may especially point out that it must remain in the discretion of the magistrate whether a fine should be inflicted in any particular case and if so what the amount should be

### TUESDAY FEB 18TH

### *The Army Medical Service*

Dr **THOMPSON** asked the Secretary of State for War if his attention had been called to a recent statement of Dr C Ball of Dublin a member of the Advisory Army Medical Board, respecting the retirement of army medical officers and would he explain whether it was the intention of the Government to recommend that an army medical officer who had served 18 or 20 years in the army and who *had failed* to pass the examination to a lieutenant-colonelcy, should be compulsorily retired on a gratuity or whether such an officer would be allowed to serve for 20 years as at present and then be retired on a pension of £1 per diem —Mr **BRODRICK** replied An officer who fails to pass the examination for the rank of lieutenant-colonel will be permitted to complete 20 years service and retire on £1 per diem —Dr **THOMPSON** asked the Secretary of State for War if, before the issue of the promised Royal warrant for reform of the Royal Army Medical Corps he would carefully consider the objections raised, both by the officers of the Royal Army Medical Corps and the Medical Schools, to the recommendations of the late Departmental Commission as regards examinations for promotion, and if he would make such alterations as would limit these examinations to the real requirements of the service —viz *for promotion to the ranks of major and lieutenant colonel*, as suggested by the sub committee appointed by the Council of the British Medical Association to consider the reform of the Army Medical Service —Mr **BRODRICK** replied The only examinations in purely professional subjects will be those for major and lieutenant colonel The examination of lieutenants for the rank of captain will be in corps and service duties only

### *The Water-supply of Knutsford*

Mr **GROVES** asked the President of the Local Government Board whether he was aware of the danger to the inhabitants of Knutsford, Cheshire, arising from the pollution of their water supply, that the medical officer of health of the urban district council had warned such council that Knutsford was liable to an epidemic similar to that which visited Maidstone, and that such opinion had been confirmed by an independent expert, and, seeing that the council had taken no steps to stop such pollution or to secure a pure supply of water, whether he would take proceedings to compel the council to fulfil its duties, and whether in view of the application to Parliament for borrowing powers by the Knutsford Light and Water Company, he would see that conditions were imposed to compel the company to fulfil its obligations and to obtain its supply of water from an unpolluted source —Mr **LONG** replied I am aware of the complaints which have been made as to the water supply of Knutsford The Local Government Board has been in frequent communication with the urban district council with regard to it The council states that it feels the responsibility of its position but that it considers that it has taken every practicable step in its power for the safety of the inhabitants of its district I am still in correspondence with it on the subject I have no control over the company by whom the water is supplied, but at my suggestion the district council has placed before the Board of Trade the facts as to the alleged pollution of the supply so that the same may be considered in connexion with the application of the company to that *department for a provisional order to enable it to raise additional* capital

## A NEW SHAVING PASTE.

MR. EDMUND WHITE recently published in the *St. Thomas's Hospital Gazette* an outline of a proposed scheme for applying aseptic principles to the barber's duties in the hospital. The scheme has proved very satisfactory in practice, but a shaving brush capable of sterilisation was wanted to make the scheme complete. In the February number of the *St. Thomas's Hospital Gazette* Mr. White returns to the subject. He says: "A little consideration will show that in shaving it is necessary to support the hairs, so that the razor may cut through them transversely, and at the same time to moisten or lubricate the surface of the skin so that the outer layers of the epidermis may not be too freely removed. ...... Numerous trials were necessary in order to arrive at satisfactory results ...... and, finally, an emulsion of paraffin wax, melting at 55° C., was adopted. This was prepared with 25 per cent. of wax and 2 per cent. of tragacanth, the wax being melted and mixed with the tragacanth previously made into a mucilage with some of the water. The addition of a little stearin or lard renders the emulsification of the wax easier, for some reason which cannot readily be explained, while about 10 per cent. of alcohol makes the preparation more agreeable to use. The fatty odour of the preparation may be covered by the addition of a half to 1 per cent. of lavender oil, and the finished product then appears as a thick white cream. In use a small quantity is rubbed over the area to be shaved and the razor immediately applied. As the water in the emulsion evaporates, the particles of wax previously distributed in the emulsion become coherent and fill up the depressions in the surface of the skin from which the hairs arise, thus forming a mechanical support during the passage of the razor. The quantity required is very small, one ounce being sufficient for shaving the face about six times."

## STERCORACEOUS THERAPEUTICS.

THERE is an inexplicable tendency in the minds of many people who are reputed sane to repose more confidence in the prescriptions of medicasters, no matter how illiterate—in fact, the more illiterate the better—than they do in those of men who have made a sufficiently deep study of medicine and the cognate sciences to be able to answer the requirements of strict, and withal practical, examiners. *Omne ignotum pro magnifico* ought certainly to be the motto of these illogical champions of uninstructed ignorance who, strange to say, are not themselves as a rule illiterate, but, on the contrary, often include in their ranks men of exceptional culture and education. Strange, likewise, but equally true, it is that the nostrums most in vogue amongst quack-salvers nearly always contain substances which, to say the least of them, are nasty. The more incongruous from an æsthetic, or, indeed, from a cleanly, point of view the vaunted remedy is, the greater are its curative virtues. It would really seem that if a budding charlatan can only hit upon something sufficiently filthy he may look upon the success of his panacea as assured. In a book entitled "Medicinal Experiments: or a Collection of Choice and Safe Remedies," of which the seventh edition was published in London by "W. Innys, at the West End of St. Paul's," in 1731, the author, according to the title-page, being none other than "The Honourable R. Boyle, Esq., late Fellow of the Royal Society," there are among its "Five Hundred Choice Receipts" a great many containing such inconceivably loathsome ingredients that the wonder is how they could ever have been thought of. Here are some textual specimens: Pigs-Dung; Earth-Worms; Paracelsus's Zebethum Occidentale (viz., human Dung); Millepides (in English by some called Wood-lice, by others Sows); the Patient's own Urine, newly made; fresh Stone-horse Dung; Pizzle of a Stagg; Highly Rectify'd Spirit of Man's Urine; Snail-shells; the Warts that grow upon the hinder Legs of a (Stone) Horse; Balls of fresh Horse-dung; House Snails; Grated Pizzle of a Hart or Deer; Oil of Earth-Worms; Sole of an old shoe; Album Græcum or Dogs-turd; Hens-dung, dry'd and mix'd with Sugar; fresh Sheeps-dung; fresh Cow-dung; Pizzle of a Green Turtle (or Tortoise); The Thigh-bone of a hang'd Person; The Powder (whether made by filing, rasping, or otherwise) of the Sound Skull of a dead Man; fresh Dung of a Hog, Vipers reduc'd to fine Powder; Frogs-spawn; &c. It would serve no useful or edifying purpose to disturb this ancient manure-heap if it were not that a tendency towards what we may perhaps call stercoraceous therapeutics still exists. In the *Morning Post* of Jan 8th, 1902, the following passage will be found under the heading, "Discovery and Invention'.—

> "The methods of native 'medicine men' are always matter for ridicule, sometimes too freely bestowed, among ourselves. A medical paper gives an account of the remarkable healing of wounds among the Kaffirs, and quotes the case of one of these having been shot, in mistake for a belligerent, by a sentry. The Lee-Metford ball passed between the ribs on his right side, went through the liver, and came out on the left under the last false rib His native doctor, having first blown well into the wound through the hollow horn of a cow, put on two plasters of cowdung. Unfortunately, in the interests of science, though the man's condition was good and his temperature low on the fourth day, a regimental doctor saw the patient and substituted antiseptic bandages in place of the plasters, with the result that, after a brief relapse of suppuration, the patient mended. It is impossible, however, to assign the respective shares in the cure to the plaster and bandage."

The Honourable Robert Boyle, who has been styled the "father of modern chemistry," was a firm believer in the virtues of stercoraceous therapeutics, and it is evident from the views implied as well as expressed by him that the writer in the *Morning Post* shares the belief of his eminent predecessor. He thinks the interests of science have suffered because the wounded Kaffir's cow-dung plasters were ruthlessly torn from him. He is mistaken, but he errs in good mediæval company.

## A CURE FOR WARTS.

*To the Editors of* THE LANCET.

SIRS,—If "At My Wit's End," whose inquiry as to the above appeared in THE LANCET of Feb. 8th, p. 420, will apply the following to his patient's warts twice daily they will soon disappear:—℞. Papain, ʒss.; acid. hydroch. fort., ʒi. Care must be taken that the mixture is only applied to the warts.

I am, Sirs, yours faithfully,
THOMAS DUTTON.

Manchester square, W, Feb. 8th, 1902.

*To the Editors of* THE LANCET.

SIRS,—I have found the liq. hydr. nitratis acidus a useful escharotic.

I am, Sirs, yours faithfully,
J. G. CARRUTHERS.

Feb. 11th, 1902.

ERRATUM.—In Dr. Castellani's article "On Hæmolysins produced by Certain Bacteria," published in THE LANCET of Feb. 15th, p. 440, the words within parentheses "(bacillus typhi, bacillus coli, and bacillus dysenteriæ of Kruse)" in the first few lines of the text should have appeared in the title and not in the text.

COMMUNICATIONS not noticed in our present issue will receive attentio in our next.

# Medical Diary for the ensuing Week.

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY** (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.) St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY** (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**WEDNESDAY** (26th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY** (27th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**FRIDAY** (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.). West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (2.30 P.M.).

**SATURDAY** (1st).—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

## SOCIETIES.

**MONDAY** (24th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish square, W.).—8 30 P.M. Council Meeting Night. Papers:—Dr. M. Skerritt: Cardiac Pain.—Dr. H. D. Rolleston: Note on Hypostatic Albuminuria of Splenic Origin.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square, W.).—7 P.M. Council. 8 P.M. Communications:—Mr. W. G. Nash. Sarcoma of the Submaxillary Gland proving rapidly Fatal.—Mr. J. Bland Sutton: Anomalous Tumour of the Antrum. Paper:—Dr. H. Campbell · The Influence of Mastication on the Jaws and Appendages.

**TUESDAY** (25th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8 30 P.M. Mr. C. Ballance and Dr. P Stewart: Clinical and Experimental Observations. introducing Discussion on the Regeneration of Peripheral Nerves (with lanter epidiascope, and microscopical demonstrations).

# Notes, Short Comments, and Answers to Correspondents.

## HOW DISEASE IS SPREAD

A CASE of small pox diagnosed in one of a number of tramps sleeping at the East Grinstead workhouse on the night of Feb 13th indicates the great need which there is for the Local Government Board to issue an order giving masters of workhouses power to detain and to vaccinate tramps when in the opinion of the medical officer such a course is desirable in the interests of public health 16 casuals presented themselves for admission to the workhouse but before their request was granted they were examined by a medical man—a course very wisely adopted by the board of guardians since the prevalence of small pox in other parts of the county 15 passed the medical officer Mr T J P Hartigan who however discovered the sixteenth to be suffering from small pox and furthermore he was of opinion that the disease must have been apparent for at least four days In the course of these four days the itinerant had slept in the casual wards of two workhouses and no doubt had associated with many more of his own class and another night he passed in a stable or an outhouse The necessary processes of disinfection were immediately carried out and the patient was isolated in a temporary small pox hospital But what of the other 15 casuals? The medical officer would have liked to have isolated and revaccinated them For the want of the necessary authority he could not so act against their will and having performed the prescribed task of work the casuals were allowed to go to wander where they liked and probably to spread infection

At a meeting of the Chichester Board of Guardians held on Feb 14th the Rev W A Firth moved that all casual paupers should until further notice be examined by a medical man before admission to the workhouse The clerk replied that this would be impracticable If such an examination can be held at East Grinstead we see no reason why a similar one should not be held at Chichester

## EGYPTIAN CIGARETTES

MESSRS W J BAMBRIDGE AND Co of 37 St Mary Axe London E C have submitted for our inspection and analysis a sample box of Loulpoulo and Co s Egyptian cigarettes which are stated to be made from the finest Turkish tobacco and to be quite free from any artificial flavouring We found the tobacco to be of an excellent Dubec type yielding on burning a pleasing aromatic odour free from pungency We could detect no flavour other than that of well matured Dubec leaf The pleasing characteristics of this tobacco would in our opinion be better appreciated if the cigarette were made not so small It would be an advantage if the cigarette could be made twice or even three times as thick so as to reduce to a minimum the amount of paper wrapper in relation to the tobacco

## AN OPPORTUNITY

*To the Editors of* THE LANCET

SIRS —Having too many hobbies I am disposing (at Stevens s auction rooms King street Covent garden) of a superb 10-inch "Apps Newton" induction coil which certainly has not had in all half an hours use and is perfect in every particular It will give a spark up to 11½ or 12 inches The cost net was (with cabinet) £40 2s 6d The instrument can be purchased on the understanding that Messrs Newton the makers will work the coil if desired and certify to its excellence This they will do There may be some medical correspondent or hospital on the look out for such an instrument which at anything below its net cost would be a bargain The coil might well be sold as absolutely new

I am Sirs yours faithfully

30 Linden gardens Bayswater W E DOUGLAS FAWCETT

## INCENSE AS AN AID TO THE TREATMENT OF INFLUENZA

*To the Editors of* THE LANCET

SIRS —I have had remarkable success by the burning of incense (pulv thus co) freely in the rooms of my influenza patients It is very useful in both recent and old-standing catarrhal cases—an antiseptic used in the days of Solomon

I am Sirs yours faithfully

Hampstead N W G PORTER WORNUM

## WEIGHT CHARTS

MR H D KELF of St Saviours Union Infirmary East Dulwich grove has devised an ingenious pattern of weight chart on which a patient s weight may be recorded and preserved in a form convenient for reference Three charts make a set the first being arranged for weights not exceeding three stones increasing by successive additions of half a pound the second is intended for weights from three to nine stones and the third for weights from eight to 14 stones The charts have horizontal rulings with the weights printed on the left hand margin and vertical rulings with spaces for entering the date at the top They are supplied by Messrs Maw Son and Sons Aldersgate-street London E C and are sold at 18s per 1000 or in smaller quantities at a slightly proportionate increase

## INDECENT ADVERTISEMENTS

A CORRESPONDENT sends us the cover of *Illustrated Bits* for the week ending Feb 22nd and invites our attention to certain of the advertisements We regret to see that advertisements are published in this paper of Martin s apiol and steel pills and of Dr Davis s Boon to Womankind Ineffective as these kind of abortifacients almost invariably are they are sold to women as safeguards against pregnancy and no newspaper should assist in the traffic Other advertisements of any special article in rubber goods of medical and surgical requisites and of tablets providing new life for weak men would not we feel sure be accepted by an editor jealous for the good reputation of his journal

## THE GRADUAL DEVELOPMENT OF FAHRENHEIT S THERMOMETRIC SCALE

IN the February number of *Knowledge* Sir Samuel Wilks relates some interesting particulars in the history of Fahrenheit s thermometric scale on which the freezing and boiling points are marked 32° and 212° respectively This scale in its original form was invented by Sir Isaac Newton whose paper on the subject is to be found in the Philosophical Transactions for 1701 Sir Samuel Wilks continues his narrative as follows —

> His [i e Newton s] lowest point was that of freezing as his highest was that of boiling water He chose for the starting point on his scale the heat of the human body and this he called by the round number 12 that is he divided the space between the freezing point and the temperature of the body into 12 parts A few years afterwards when Fahrenheit was working at the subject of heat he took Newton s instruments for his experiments but finding the scale not minute enough he divided each degree into two parts and so made it measure 24 instead of 12 He also did more for finding he could obtain lower temperatures than freezing and notably that of ice and salt mixed together he took this for his starting point It was from this point he began to count 24 degrees up to body heat This made by his measurements 8 the point of freezing Boiling point he made 53 It then became zero freezing 8 body heat 24 and boiling water 53 Later on finding that he could measure increments of heat more minutely Fahrenheit divided each degree into four parts It will now be seen that if the numbers just mentioned are multiplied by four we have the thermometer which is now in use Beginning with zero freezing becomes 32 the body heat 96 and boiling point 212 This is the scale which Fahrenheit made and the reasons for his doing so

## A PLEA FOR THE SEALED MILK CAN

*To the Editors of* THE LANCET

SIRS —In your annotation on the above subject in THE LANCET of Feb 8th p 391 you mention that it has been stated pretty freely in court that the railway companies will not allow milk consignors to seal or lock their cans This statement shows to my mind that the persons responsible for it either were hopelessly behind the times or had some ulterior object in making it

For upwards of 20 years this company has insisted upon all milk churns consigned to them being sealed and not the slightest opposition or objection has been raised to the practice by any of the railway companies Of such importance have we deemed this simple precaution that no contract has been entered into for at least 20 years which has not contained a clause imposing a penalty for the omission As a result we have never among the millions of cans we have received in the period had a single case of tampering with the milk in transit

I am Sirs yours faithfully,

M HATTERSLEY

Managing Director of the Aylesbury Dairy

Bayswater W Feb 8th 1902 Company Limited

# EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS,' and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

*It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this Office*

*Lectures, original articles and reports should be written on one side of the paper only* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication*

*We cannot prescribe or recommend practitioners*

*Local papers containing reports or news paragraphs should be marked and addressed To the Sub Editor*

*Letters relating to the publication sale and advertising departments of* THE LANCET *should be addressed* ' *To the Manager*

*We cannot undertake to return MSS not used*

# MANAGER'S NOTICES.

### THE INDEX TO THE LANCET

THE Index to Vol II of 1901 which was completed with the issue of Dec 28th and the Title page to the Volume, were given in THE LANCET of Jan 4th

### VOLUMES AND CASES

VOLUMES for the second half of the year 1901 are now ready Bound in cloth, gilt lettered, price 18*s*, carriage extra

Cases for binding the half year's numbers are also ready Cloth, gilt lettered price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

### TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free either from THE LANCET Offices or from Agents, are —

| FOR THE UNITED KINGDOM | | TO THE COLONIES AND ABROAD | |
|---|---|---|---|
| One Year | £1 12 6 | One Year | £1 14 8 |
| Six Months | 0 16 3 | Six Months | 0 17 4 |
| Three Months | 0 8 2 | Three Months | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch') should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE It has come to the knowledge of the Manager that in some cases higher rates are being charged on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates on this or on any other ground, should be resisted The Proprietors of THE LANCET have for many years paid and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER THE LANCET OFFICES 423, STRAND, LONDON ENGLAND

rule about two months before birth. In spite of this it is a fact that the testis would seem to pass into the area of the femoral triangle even as late as commencing adult life. It is not clear, therefore, that the gubernaculum can always be said to have the credit of having caused the abnormal position.

It is extremely doubtful whether the testis has ever reached the upper part of the thigh by a spontaneous passage through the femoral ring. The classical instances which are quoted in support of this view are not altogether convincing as to the exact path along which the testis moved, some of the cases being very inadequately reported. Nearly always with the testis in Scarpa's triangle the spermatic cord can by careful manipulation be traced, not through the femoral ring, but up to and through the superficial abdominal ring, thus proving that the organ left the abdomen by the inguinal canal, and it was only after its exit from the superficial abdominal ring that it passed into the upper part of the thigh. That a hernia in its advance may force a testis from its normal course into a position which is altogether unusual for it, is fairly certain, and most, if not all, of those instances in which a testis is found lying on the aponeurosis of the external oblique muscle superficial to the inguinal canal are in reality examples of this pushing and not of the drawing action exerted by fibres of the gubernaculum.

Into whatever position the testis unnaturally passes it takes with it a process of peritoneum termed the processus vaginalis testis, provided that the pouch remains connected with the general peritoneal cavity, or the tunica vaginalis if it is shut off from it.

While thus reviewing the imperfect and the abnormal descent of the human testis it is well to remember in connexion with the pathological conditions that may be associated with the same that what may be imperfect or abnormal descent in the human subject may be the natural or perfect condition in other animals. Taking only the vertebrata in which the testis has an inclination to descend it will be found that the testis remains permanently within the abdomen near to the region of the kidney in certain animals, of which the snake, the pigeon, and the frog are typical examples. In these, therefore, there is practically no descent whatever. In the hedgehog, on the other hand, while the testis does certainly continue to reside within the abdomen, yet it has descended so far as to lie close to the deep ring, the entrance to the inguinal canal. Here there is an attempt to reach the region of the scrotum, but it is an abortive one. In the hare the testis has left the confines of the abdominal cavity and is placed in the inguinal canal, which indicates a still further attempt to descend.

In those animals other than man in which the testis has reached the scrotum it may still retain some indication of imperfection when compared with the human subject. In apes, for instance, it is the rule that the processus vaginalis should permanently remain patent. In the pig the testes normally pass into the perineum, the scrotum never being distended, while in the marsupials they occupy a position which is pre-penial.

It is also worthy of note that the position of the testis in some animals is not permanently scrotal, but that the organ descends only during the period of annual sexual activity into this pouch, being withdrawn again into the abdomen or the inguinal canal when this season is over. Further, in some other animals the testis, which is of comparatively small size ordinarily, becomes considerably enlarged during the breeding season, returning to its more usual size when the period is past. The actual size of the testis compared to the weight of the animal to which it belongs varies greatly in different classes. In many carnivorous animals, as, for instance, in the cat or the dog, the testes are relatively small. Herbivorous animals, such as the goat and the ram, on the contrary, have proportionately large testes. In the human subject the testis that has normally descended into the lowest part of the scrotum is fully developed, but if it should be arrested then there is a great probability of imperfect development. But, on the other hand, in those animals in which the testis naturally lingers in its descent or does not even start to descend the development of the organ will be perfect. There is, therefore, some subtle influence at work in the testis of the higher vertebrates which renders full descent in the vast majority of cases necessary to, or concomitant with, full development. It is also a fact that the various pathological conditions associated with imperfect descent in the human subject are unknown, or almost unknown, in those animals in which the testes never transgress the limits of the abdominal wall.

The effect of imperfect descent upon the testicle itself, so far as its anatomical characters are concerned, lies chie in the fact that, as a rule, the organ is smaller than normally-placed fellow, or, at any rate, smaller than a tes should be of an individual of the same age whose testes in their proper position. While, however, it is a truth tl the testis is so frequently not of its usual magnitude wher is imperfectly descended, yet it must be remembered tl this want of growth is not invariable and that about 5 cent. are of normal size in spite of their occupying situati other than the lowest limit of the scrotum. This proporti is undoubtedly a comparatively small one, and even in the without confirmatory microscopical examination of glandular structure, it is impossible to be quite certain tl the testis, although apparently of its proper size, has not ultimate tissue imperfect in its development.

There are at least three ways in which the abnormal cc dition of the imperfectly descended testis can be view The first is that there has been an initial want of pro formation of the organ altogether apart from the want complete descent. The second is that the organ proceeds its usual growth up to the period of the commencement sexual life, but never enlarges and undergoes that f development which should accompany the onset of pubert The third is that the testis does acquire its normal size a with it its complete physiological function at puberty, b that owing to its abnormal position it is soon involved retrogressive changes, producing in the end entire atrop of the seminal tubules and a consequent loss of activit It must be confessed that there is still a want of cle evidence in favour of any one of these three suggestions, a it may be possible that each should have its quota of cas placed under its respective heading.

The testis as it lies in the abdomen close by the kidney, the iliac fossa, or just within the deep abdominal ring, when it has passed into, but not out of, the canal, or, furth when it has only reached just below the superficial ring, the upper part of the scrotum, is undoubtedly in the majori of instances smaller and softer than a normally plac organ. In shape the arrested testis may closely resem that of the perfect organ, or it may widely differ therefro If the epididymis has passed beyond the site of the body the testis this condition will materially alter its sha Moreover, its internal structure on section contrasts marke with that which is fully developed.

Of recent years a considerable amount of attention been paid to the want of development of the imperfec descended testis, chiefly from the fact that there has b much difference of opinion as to what is the correct met of dealing with the organ when it is met with in the cou of a radical operation upon an associated hernia. From review of a large number of records, both published unpublished, as well as from the examination of a consid able series of sections of imperfectly descended testes, a the exact condition of the seminal tubules, of the presenc not of spermatozoa or of their partial formation, it wo seem that it may be accepted as a working hypothesis t the testis so arrested is one that has very definite divergen from the structure of a normally placed and fully-develo organ. A fully-developed normal adult testis may described as having well-marked seminal tubules show spermatozoa in all stages of their formation. The walls the tubules are composed of several layers of flattened ce well formed and regularly arranged. The tubules occupied by epithelial elements, grouped as irregular str They may be said to form three fairly distinct layers. outermost, or lining, layer is made up of cubical or slig flattened cells which lie immediately within the ba ment membrane of the wall. Some of these may h and there show some evidence of proliferation. next layer consists of large rounded cells with cl protoplasm which are also somewhat irregularly plac These are the cells which are chiefly concerned, it probable, with the formation of spermatozoa. They n be termed the intermediate or proliferating cells. innermost layer is one of granular ill-defined cells wh appear so closely associated as to produce an almost unif mass, staining badly and showing no tendency whatever division. Their nuclei are small, and towards the lumen the tubule they become very faintly outlined. This mass cells may be looked upon as the nutritive layer. Embed in the inner part of this stratum are the heads of spermatozoa, and it is probable that these become freed the liquefaction of the protoplasmic layer in which th heads are concealed. When, on the other hand, the struct

## LECTURE I

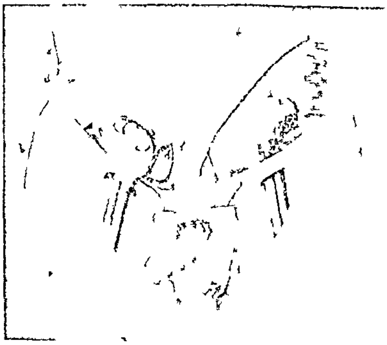
*Delivered on Feb 24th*

Mr President and Gentlemen, — The imperfectly escended testis has during recent years claimed an ncreasing amount of attention and while there has not een advanced much that is novel, yet the importance of he lesion from a surgical point of view has been more learly demonstrated It is my intention in these lectures o bring together the chief facts so far as they are known at he present time concerning the anatomy, physiology, and athology of the testis which has not reached its normal osition in the scrotum

### Anatomy

The human testis may be arrested at some spot in the ormal route along which it migrates—namely, within the bdomen in the inguinal canal just below the superficial bdominal ring and in the higher part of the scrotum Fig 1) These constitute non descent partial descent, or retention Or the testis having proceeded as far as the exit of the inguinal canal may pass into an unnatural position such as the perineum Scarpa triangle the root of the penis or upon the superficial surface of the aponeurosis of the external oblique muscle of the abdomen These constitute abnormal descent or ectopia (Fig 2)

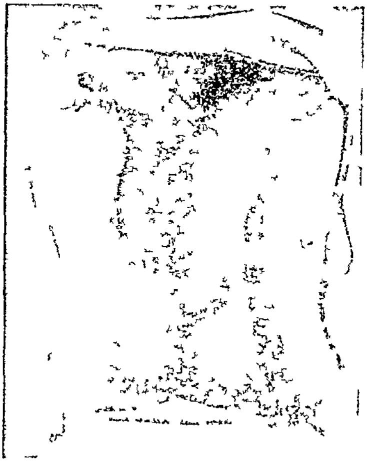
Fig 1



Inguinal retention of both testes a Unopened processus vaginalis of left side b Opened processus vaginalis of right side d Fibres of internal oblique (Bredall 1824)

It would occupy too great an amount of time to do more than indicate the several conditions which have been considered to be the causes of the arrest of the human testis in its passage along the normal route of its transition For the sake of brevity they may be classified as follows 1 Conditions associated with the mesorchium (*a*) the mesorchium may be too long, the testis would therefore probably hang too freely in the abdominal cavity and would thus be prevented from engaging the ostium of the processus vaginalis (*b*) adhesions between the peritoneum forming the mesorchium and the adjacent portion of the serous membrane, generally the outcome of intra uterine fœtal peritonitis, and (*c*) abnormal persistence of the plica vasculari 2 Conditions associated with the testis and its component parts (*a*) the spermatic vessels may be too short, (*b*) the vas deferens may be of insufficient length, (*c*) the epididymis may be abnormal in size (*d*) there may be a fusion of the two testes—synorchism, and (*e*) certain forms of hermaphroditism 3 Conditions associated with the gubernaculum testis (*a*) absence of the upper normal attachments of the gubernaculum (*b*) deficiency of its muscular fibres, and (*c*) deficiency or absence of its scrotal attachments 4 Conditions associated with the cremaster (*a*) retraction of the testis after it has descended to its usual habitat in the scrotum, and (*b*) want of action of the internal fibres of the cremaster before the testis has reached the inguinal canal 5 Conditions associated with the route along which the testis has to pass (*a*) ill development of the inguinal canal, (*b*) ill development of the superficial abdominal ring and (*c*) ill development of one half of the scrotum 6 Other conditions such as the wearing of a truss preventing the onward passage of the organ into the scrotum In some cases the body of the testis may be retained in the canal, while the epididymis and vas pass into the scrotum

Fig 2



A left testis lying in the perineum The testis was of the size of an almond and its component parts could be readily made out through the skin The left half of the scrotum was entirely undeveloped The right testis was of normal size in the right half of the scrotum (Godard)

There are probably only two causes of the abnormal descent of the human testis, or ectopia of the organ one is that the testis is drawn into its unusual position by the traction of certain sets of fibres of the gubernaculum testis, the other is that the testis is pushed into its abnormal site by an advancing hernia. In connexion with the first it is necessary to remember that the lower attachments of the gubernaculum are not only into the tissue at the bottom of the scrotum but that there are also at least three other additional sites in which they may terminate These accessory fibres may be of a permanent nature or only transitory in their existence The actual regions in which they have been observed are the perineum, Scarpa's triangle about the root of the penis and towards the anterior superior spine of the ilium in front of the aponeurosis of the external oblique muscle of the abdomen Those fibres which pass into the perineum may terminate by the side of the anus, may blend with the external sphincter ani or may be attached to the ramus of the ischium With regard to the fibres which pass into the neighbourhood of Scarpa's triangle they are fairly constant but are only found at a comparatively early stage of intra uterine life, disappearing as a needful for growth of the body, ought to show signs of hypertrophy. Yet a size of the normally placed organ greater than it should be in a person of corresponding age and development is but rarely seen in the human subject In animals, on the other hand, there seems to be more evidence of such a compensatory hypertrophy. This is particularly the case in the stallion. Sometimes in this animal the descended organ may reach twice the bulk of a normal testis in a horse of the same age and size. Because, therefore, in the human subject true hypertrophy of the fully-descended testis when its fellow is arrested is a comparatively rare condition it still remains to determine whether the completely descended and fully-developed organ, although not larger than normal, is capable by itself of supplying the needed stimulus for adequate bodily growth, or whether the arrested testis that is also present has to subscribe its share towards the same result.

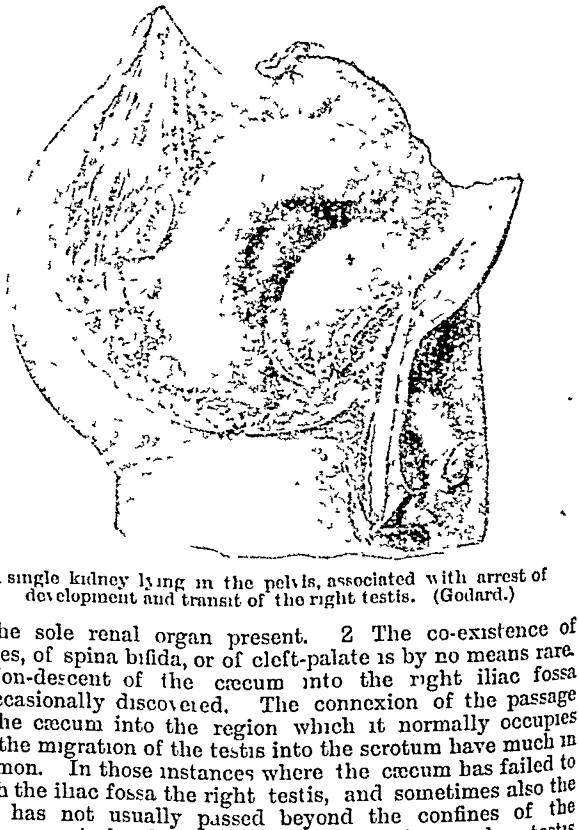
The matter becomes one of serious import when the question of the removal in early life of the imperfectly descended organ is under consideration Experience has shown, and that fairly conclusively, that a single well-developed testis is sufficient in itself to provide all that is needed for the proper growth of the individual, and that no serious inconvenience to the patient, so far as complete bodily growth is concerned, is likely to occur should it become necessary to remove its fellow, and this in spite of the fact that the organ which is left does not exhibit any tendency to increase in size. In furtherance of the argument that an ill-developed and imperfectly descended testis does not subscribe much, if any, of the stimulus for full bodily development of the man is the fact that in instances of double arrest and non-development of the testes there is as a rule some failure in the growth of the individual in all directions. It is to be understood, however, that this want of growth may be due to some prior cause which is acting as a factor in also producing the imperfect descent Such a condition is commonly seen in cases of cretinism and in those rare instances of the condition which it is proposed to term "ateleiosis." When both testes are arrested, but are not imperfectly developed, there should be no want of bodily or other development

In endeavouring to determine the causal relationship between imperfect development of the arrested testes and the failure of general bodily growth, or of efficiency in certain physiological functions, some light may possibly be thrown by a careful study of the microscopical appearances of sections of the arrested glands As was stated in the former lecture, it is an interesting fact that the testis of the boy before puberty is entirely devoid, or nearly so, of a type of cell lying in the spaces between the seminiferous tubules These interstitial cells are, however, beginning to be noticeable about the period of increased sexual development and may become very abundant. It has further been shown that although in instances of double arrest of the testes both organs may be wholly incapable of producing spermatozoa, yet the owner of them may acquire full virile power, but will remain for ever without the ability to procreate The arrested glands not infrequently have large numbers of these well-defined interstitial cells, and it is possible that they have an important function at the onset of puberty. They may have the duty of producing what is now so generally termed the "internal secretion" of the organ. This substance, whatever it may be, probably plays an important rôle in the development of the body, for without its presence much of the normal growth may be lost or the usual changes that occur at puberty may be profoundly modified. That there is some relationship between internal secretion of glands and the growth and division of cell elements gains some support from the fact that in a considerable proportion of instances where double oophorectomy has been performed for recurrent or inoperable carcinoma of the mamma, and particularly in women before the climacteric, there has been a very noticeable change in the constitution of the malignant deposits In some of these cases the neoplasm has become markedly altered within a few days of the removal of the ovaries, and in others, well-authenticated, there has been a complete temporary, if not a permanent, disappearance of the carcinomatous masses. Then, again, there is the well-known circumstance that an early removal of the ovaries leads to a diminution in the size of the uterus—uterine atrophy; and that the ablation of both the testes causes shrinking of both lobes of the prostate—prostatic atrophy. Further, it is an interesting fact that each of these mutilations is liable to be followed soon after they are performed by severe "nerve-storms," in which the patient may for the time being become irresponsible for his or her actions. On the other hand, supposing in the male that the vasa deferentia alone have been severed, such nervous phenomena but rarely succeed; and in such a condition, although eventually the testis does atrophy on the side of the vasectomy, yet it remains present and probably still capable of producing its internal secretion. Further, a removal of both the testes or of both the ovaries tends to a considerable alteration in the amount of adipose tissue in the body, the subjects as a rule becoming much disposed to the accumulation of fat in the subcutaneous tissues There is much that is highly suggestive in the fact of these internal secretions, but there is need of a large amount of clinical, physiological, and pathological study to elucidate their full significance.

Returning again to the theory that in some instances the association of imperfect descent of the testes with a failure in perfect growth may be due in reality to some common cause, cretinism is perhaps the best example of such. In male cretins it is extremely rare to find either of the testes within the scrotum, and it is equally rare to find them at all developed, and although I have not as yet had the opportunity of examining the testis of a cretin by the microscope I should expect that the interstitial cells are altogether wanting in their development. Thus it may be stated shortly that whereas there are found in the testis two distinct types of cells, the first needed for the formation of spermatozoa, and the other probably, though it cannot at present be affirmed positively, required for the production of an internal secretion, and failure in the development of both these types of cells will as a rule lead to failure in the proper bodily growth of the individual, but development of the interstitial cells, even though there are no sperm elements, will allow the possessor to become virile while remaining sterile.

Many cases are on record in which imperfect descent of the testis has been accompanied by actual bodily deformities Among the more interesting and important of these are:—1 The occurrence of incomplete transition with the absence of one kidney (Fig. 5). In one such case a sarcoma of the arrested testis actually produced a fatal result by extension to the sole renal organ present. 2 The co-existence of talipes, of spina bifida, or of cleft-palate is by no means rare. 3. Non-descent of the cæcum into the right iliac fossa is occasionally discovered. The connexion of the passage of the cæcum into the region which it normally occupies and the migration of the testis into the scrotum have much in common. In those instances where the cæcum has failed to reach the iliac fossa the right testis, and sometimes also the left, has not usually passed beyond the confines of the abdomen As has been pointed out, the gubernaculum testis has anterior attachments to the cæcum, &c, and these share probably in bringing about some of the movement of the

FIG. 5.



A single kidney lying in the pelvis, associated with arrest of development and transit of the right testis. (Godard.)

of the tubules of a testis that has not reached its proper level is examined there will be found a very different histological picture in the majority of the instances. The tubules are fewer in number, smaller, and more widely separated from one another by interstitial tissue, consisting of loose connective tissue which is rich in blood-vessels in spite of the otherwise ill-development of the gland. Scattered throughout this will be seen nuclei belonging almost certainly to interstitial stroma cells. (Figs. 3 and 4.) In some sections these appear to have undergone considerable *increase* both in number and size. *Such* interstitial cells are present in the connective tissues of the normal adult organ, but in comparatively few numbers. What their significance and function may be is still problematical. Possibly they are associated with an internal secretion of the gland, a secretion that may be needful for the full bodily development or sexual perfection of the man. The fact that they are found in apparently larger numbers in particular instances of imperfectly descended testes is a matter of great interest both from a physiological and a pathological point of view. The connective tissue, moreover, here and there contains some large lymph spaces. The basement membrane of the tubules derived from the connective tissue as well as the membrana propria are well-developed. The lumen of the tubules is most commonly found occupied by a mass of granular débris containing a large number of nuclei of various shapes and sizes, these being probably separated from the cells lining the tubule. As a rule, neither spermatoblasts nor spermatozoa can be demonstrated in the tubules of imperfectly descended testes. In some instances, however, it is possible to show that there has been actual spermatogenesis, and this most usually in those testes which have passed into the perineum.

## LECTURE II.

*Delivered on Feb. 26th.*

### PHYSIOLOGY.

MR. PRESIDENT AND GENTLEMEN,—Nearly all authorities are agreed that the testis which has not reached its normal position in the scrotum is generally functionless—at least, in so far as the formation of spermatozoa is concerned. While, therefore, there is no doubt that this belief is true in the vast majority of instances, yet there are persons whose testes, although arrested or ectopic, are nevertheless capable of producing well-formed and active spermatozoa. This fact has been indubitably proved by the microscopical examination of the semen which has been ejaculated and of the lining epithelium of the tubules of the glands themselves, in addition to the evidence of the procreation of children.

Double arrest or ectopia associated with want of development of the testes as a rule implies sterility on the part of the man, although he may be perfectly virile. There is also some real doubt as to whether a testis arrested at birth, but brought down in early life into the scrotum, ever so develops as to become the seat of spermatogenesis. A few cases are on record *in which this has been stated to have occurred*, but the facts given do not support the assertion strongly. Moreover, testes which at birth are lying in the inguinal canal or even within the abdomen have been known to descend gradually or perhaps somewhat hastily either before or after the period of puberty. It may therefore be that some of the glands that have been brought down, placed, and grown in the scrotum were those which, although well-developed for their age, had merely had their passage delayed and would eventually have reached their proper habitat by natural means and have become fully capable of function. But while the chief fault of the imperfectly descended testis may be its inability to produce active spermatozoa there are other conditions so closely associated with arrest or displacement of the organ that they require some description. There would appear to be some relationship between the general growth and development of the body in the male and a proper descent of the testis, or, to put the same statement in slightly different language, many instances of want of general growth of the body are accompanied in the male by an arrest of the testes. The subject may perhaps be amplified by the following propositions. 1. Arrest of one testis, with complete descent and development of the opposite gland, is only very rarely associated with any deficiency in bodily growth. 2. Arrest of both testes, when they are ill-developed, is usually accompanied by some more or less pronounced want of development of the body as a whole 3. Arrest of both testes, but good development of both glands, is but rarely followed by, or connected with, imperfect growth of the body. 4. Arrest of both testes with want of development of only one gland is not necessarily accompanied by a diminution of bodily growth. With one testis arrested and ill-developed there is therefore, except in a few instances, no lack of development of the individual, whether bodily, mentally, or sexually. It would seem from *this fact that either* the fully-descended and developed testis is sufficient to promote bodily growth, that it has in reality at present some obscure qualities or functions that render it capable of playing an important rôle in the organism in spite of its fellow being functionless, or that, on the other hand, the arrested gland does of itself supply its quota towards the full development of the individual. If the former view is the correct one it might be urged that the normal testis, in order to supply the full amount of what is and the abnormal features of the external genitals may both be the result of some prior cause. A lack of some form of stimulus to proper development may have affected the whole of the generative apparatus, bringing about the arrest in the descent of the testes and the want of full differentiation of the external organs as male.)

## PATHOLOGY.

*Inflammation of the imperfectly descended testis.*—The testicle which has not reached the lowest limit of the scrotum, or which has passed into abnormal positions, is liable to inflammation arising from the same causes as the inflammatory conditions of the normally descended organ. But in addition the site of the testis when arrested or ectopic in itself renders it prone to become inflamed from reasons other than those operating upon the normally placed gland. Inflammation of the imperfectly descended testis may be due, therefore, to (1) traumatism; to (2) extension of inflammation from the urethra; to (3) secondary inflammation in certain cases of parotitis (in all of these the inflammation is of an acute nature); to (4) deposit of the tubercle bacillus; or to (5) syphilitic infection (in both of these it is usually of a chronic nature).

*Traumatic inflammation.*—Inflammation due to traumatism is peculiarly the misfortune of the testis which is abnormally situated. A testis hanging from a normal cord in the lowest part of the scrotum, although apparently exposed to many and grave dangers, is in reality comparatively seldom actually damaged, for it is well able to get out of harm's way. It is so mobile that it slips aside almost at the approach of violence. Not so the testis which hangs high in the scrotum or just below the superficial ring, often from a short, altogether unyielding, cord, or the gland which is retained in the inguinal canal. When it has only passed out of the canal but a short way the testis is so placed as to be constantly open to receive blows and various forms of harmful pressure, which it is unable to avoid in the manner that its normally placed fellow can do. Many a time the delicate and sensitive testicular tissue is pressed backwards against the totally unyielding body of the os pubis, only to result in a sharp attack of acute orchitis. It is here also, outside the inguinal canal, but not in the scrotum that the imperfectly descended testis is certain to be injured by the pressure of the pad of a truss that has been improperly applied. When an inguinal hernia accompanies a testis found just below the superficial abdominal ring, the pad of the truss which is to control it should be placed over the site of the inguinal canal and altogether above the level of the body of the os pubis. Here it will rest only upon soft tissues and the testis will be in no way exposed to injurious pressure. In like manner the adjustment of a truss to a bubonocele with the testis in the inguinal canal will cause no harm, as a rule, if the testis is allowed to slip away to one or other side of the pad But it may be markedly irritated in this position if a truss with a so-called horse-shoe or forked pad is applied. Fortunately, the testis has the good sense not to remain within the trap that is so placed to retain it and thus escapes injury; but should it happen to be squeezed in the restricted area prepared for it an attack of inflammation is almost certain to result. Again, with the testis in the canal damage may accrue if a truss with too strong a spring is applied, or from the pressure of an instrument the spring of which has a too-marked antero-posterior curve, as so often seen in badly constructed trusses. Inguinal inclusion is also a cause of inflammation owing to the fact that strong muscular efforts on the part of the patient will produce sufficient pressure upon the organ to set up actual injury. In many other cases the application of a trust is in reality a prophylactic measure, for it will occasion the retention of the gland within the abdomen and thus keep it to a great extent out of danger.

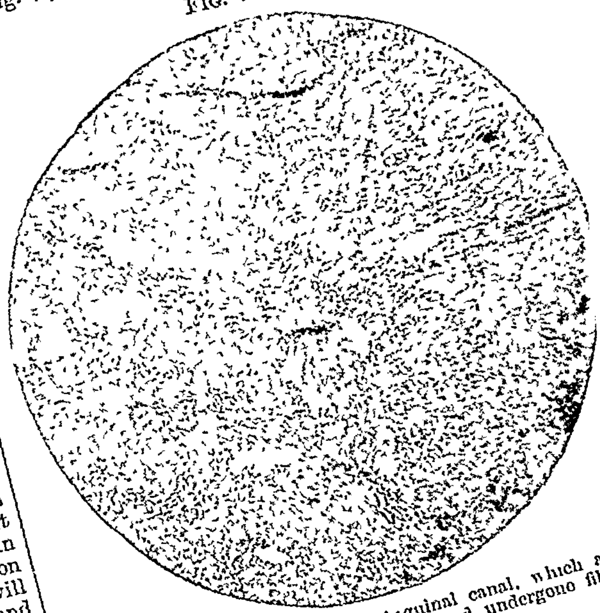
There is another manner in which a testis in the inguinal canal may be damaged. Supposing that the gland is at the lower part of the canal, and hanging from a fairly lax cord, one that allows of a certain amount of play in an up-and-down direction, a sudden muscular effort, such as the lifting of a heavy weight, may lead to the extrusion of the organ through the superficial abdominal ring, the pillars of which during the passage become separated from one another and approximate after the descent. It will thus come about that undue pressure may be exerted upon the spermatic cord, as well as possibly some actual injury to the testis in its transition. Very severe pain, sometimes enough to cause fainting, is occasioned and acute inflammation rapidly supervenes. This accident, although in some points resembling that of torsion of the spermatic cord, is distinct from that lesion and may be several times repeated, provided that the testis is withdrawn again within the limits of the canal.

Torsion of the cord, which is itself not infrequently the outcome of traumatism, is another cause of inflammation, often passing on to gangrene. When the testis has passed into the perineum it is peculiarly liable to become squeezed and bruised from pressure in sitting, horse exercise, or in bicycle-riding. The testis in Scarpa's triangle, again, is exposed to injury, but not to the same extent as the organ which lies in the perineum. The testis which has not left the protection afforded by the abdominal wall and still lies within that cavity is not more threatened with damage than is the normally-placed ovary.

Inflammation of the imperfectly descended testis consequent upon traumatism may occur at all ages but is most common in young adults. As in the normally situated gland, so inflammation of the abnormally placed organ is frequently accompanied by an acute hydrocele of the enveloping serous membrane, though on account of the usual communication of the peritoneal pouch with the general cavity of the abdomen there may be but little accumulation of fluid in the sac, for much of it will find its way upwards. In those instances where the processus vaginalis has proceeded beyond the position of the testis the fluid may fill the lower part of the sac as well, thus masking to a certain degree the absence of the testis from the scrotum and leading to some confusion in the diagnosis of the actual condition that is present. The fluid, if evacuated, is often found to be turbid or even flaky from the admixture of inflammatory products with the serous liquid.

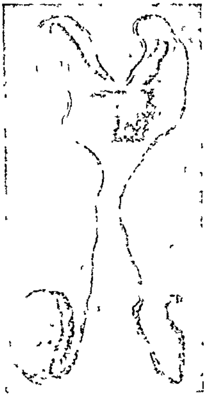
The prognosis of traumatic inflammation of the imperfectly descended testis is a grave one so far as the organ itself is concerned. Such an inflammation is nearly always the forerunner of complete atrophy of the gland, so that should it have possessed any vestige of function previously to the attack this will be lost entirely subsequently. If the disorganisation of the testicular tiss is not absolute after the primary inflammation a seco attack is almost sure to occur and lead to to destruction or the conversion of the gland into a fibr mass. (Fig. 7.) These repeated attacks of inflammation render the organ a source of great annoyance to the sufferer and may be even of danger to him. It is rare for suppuration to take place in the ordinary traumatic inflammation, just as it is also uncommon when the normally placed testis is similarly affected. The hydrocele that is often produced during the attack of orchitis may persist after all the signs and symptoms of the inflammation have passed away. A testis which has once been the site of inflammation may

FIG. 7.



Section of a testis from the inguinal canal, which after repeated attacks of inflammation had undergone fibroid degeneration bowel. In those instances in which the cæcum has remained higher than it is naturally there has been an arrest in its so-called descent, while in those cases in which there exists a congenital cæcocele there has probably been an excess of the normal traction 4. Ectopia vesicæ is almost always, when it occurs in the male, associated with imperfect descent of the testes, which, as a rule, lie in pouches on either side of the extroverted bladder. Not infrequently there is a hernial protrusion at the same time into the processus vaginalis of the arrested glands. 5. In one instance at least there has been a double penis associated with imperfect descent of the testes. There does not appear to be any evidence that arrest of the testes is accompanied by a failure in the development of the tonsils, just as there is none to justify the belief that has been held by some that excision of the tonsils is liable to be followed by atrophy of the testes. There would also, and naturally, appear to be a relationship between the descent of the testes and the sexual development of the individual. The influence of the descent and development of the testis upon the formation and growth of the accessory genital structures in the male is marked. The chief organs to be affected are the prostate, the vesiculæ seminales, Cowper's glands, and the penis. With regard to the prostate, when both testes have failed to arrive in the scrotum, provided that they also show a want of proper development, this associated structure is usually found to be small—that is to say, it does not increase in size at the onset of puberty, remaining always in its puerile condition, its fibrous tissue appears to be added to, while its glandular tissue in the form of the tubules is never fully formed, being represented merely by branching fissures doing duty for ducts and lined by a single layer of flattened cells. The intervening or inter-tubular connective tissue is hypertrophied and there are but few non-striated muscular fibres present. Further, as life advances there seems to be but little tendency for that enlargement which is so common in the organ when there has been an active sexual life. It is also true that only one-half of the prostate will be properly developed when only one testis has reached the scrotum, the other having been arrested and remained in a condition of ill-development. The vesiculæ seminales and the vasa deferentia, either unilaterally or bilaterally, according to whether one or both of the testes have failed to gain their position in the scrotum, show evidence of want of development and appear almost as if they were absent in some instances (Fig. 6) The vesicle on the side in which the testis has not descended is small, very saccular, and unfilled by semen Cowper's glands habitually fail to become of normal size where the testes have been arrested; in fact, in some instances neither they nor their ducts can be found. The penis with double arrest is as a rule small, though there are exceptions. It is also flaccid and appears frequently as if shrunken Erection may be faulty and ejaculation nearly, if not quite, absent. Not uncommonly associated with these conditions there is a want of the proper attainment of manly characteristics. The hair about the symphysis pubis shows a feminine arrangement, the pelvis tends to assume the shape seen most often in the female, and the larynx and voice remain as in the boy. Occasionally the mammary glands show distinct hypertrophy. In a few instances sexual perversion has been present.

FIG. 6.



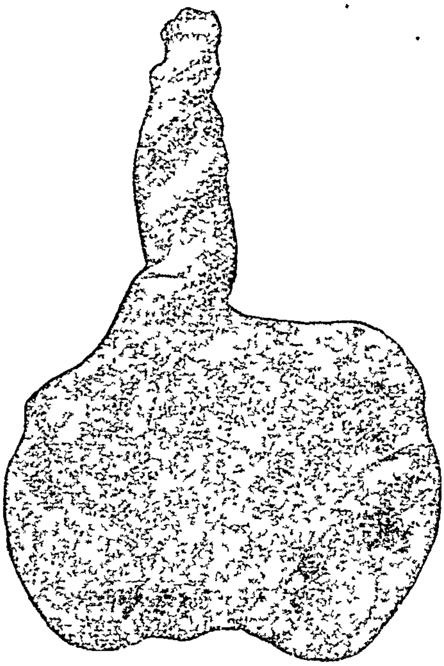
Absence of left testis with imperfect development of vesicle. (Godard.)

There is yet another relationship which is one of considerable interest. It is the association of non-descent of the testes with a condition of hermaphroditism. Hermaphroditism may be classified as true and false. In both the varieties, but particularly in the more common form of spurious, it is very usual to meet with either complete or incomplete arrest of the testicular gland. In true hermaphroditism there are present one or more testes and ovaries or glands which are a combination of both organs. Thus it is possible to have at least three forms of this variety: (1) that in which there is one ovary or testis on one side with an ovary and testis on the other—that is, unilateral; (2) that in which there is an ovary and a testis on both sides—that is, bilateral; and (3) that in which there is an ovary on one side and a testis on the other—that is, lateral. In all such cases it is a matter of some interest as to where the testicular gland is to be found. In nearly half the organ will be found either completely within the abdominal cavity or lying in the inguinal canal. There would seem, therefore, to be some relationship between the causation of the hermaphroditism and the non-passage of the male gland into the scrotum. In spurious hermaphroditism the imperfect descent of the testis is present in even a greater proportion of the cases. In this form there is an external appearance of the organs of generation of one sex, together with internal generative apparatus appertaining to the opposite sex. The relationship between the imperfect descent of the sexual gland and the abnormal condition is perhaps more readily seen and understood in this type than in the former one. Most of the instances are those in which the external parts of generation take the form more or less of the female, while the internal are in reality those of the male.

In addition to this variety there are those forms of complex hermaphroditism in which there is a mixture of the organs of both sexes externally and internally, as, for instance, that class of case where, although there are testes within the abdomen, there is also a uterus and associated parts but no ovaries. The question as to the position of the sexual glands in instances of spurious hermaphroditism should be studied, for it may throw some light on the occurrence of such conditions. In many of the recorded cases there have been found swellings in the inguinal canals. In some these have been the sexual glands, testes, arrested at this spot. In others the organs have been discovered in the bifid scrotum or in the parts which correspond to the labia majora Particular attention is directed to the swellings in the inguinal region. Where the external organs are those having the appearance of the female, more or less developed, a tender, oval, and firm body occurring in one or both of the inguinal canals is very suggestive of a hernia of the ovary There are, in fact, several instances on record in which the structure has been removed under the impression that it was such a gland, and it was only after microscopic examination that its true testicular nature has been discovered. It is doubtful, indeed, whether the opposite condition—namely, that in which the external organs are such as would lead to the belief that the individual was a male together with ovaries in the inguinal canals—is at all common, though not unknown Therefore, it may be stated that supposing there are bodies lying in the canals, associated with some doubt as to the sex so far as the external organs are concerned, it is the wisest plan to look upon the person as a male rather than as a female.

The question, then, that naturally arises is, Has this imperfect descent of the testicular gland any bearing upon the abnormal conditions of the external generative organs? It is a fact that in certain other cases where the testes have failed to reach the scrotum the penis has remained so small as to simulate an enlarged clitoris, and the scrotum has been very imperfectly developed, almost rudimentary, and with but little raphe present, and a degree more or less pronounced of hypospadias co-existent. A little further development of the same tendency to an abnormal condition of the parts and there is produced all the female characteristics of transverse hermaphroditism. Such a state may, therefore, be the outcome of some influence dependent upon the imperfect descent of the testes, or the failure to migrate on their part has allowed intestine to lie in juxtaposition These micro-organisms may lead to suppuration in the sloughing organ or to the formation of pus in the wound after the removal of the gland.

FIG 8



Strangulation of a testis due to torsion of its cord. The dark patches show extravasation of blood into its substance. (Guy's Hospital Museum, No 2078)

For the integrity of the gland torsion necessitates a very grave prognosis Even one attack of rotation, and that one only permitted to last quite a short while, say but a few hours, has been demonstrated to lead to atrophy of the testis Repeated attacks unquestionably tend to eventual disorganisation. Torsion produces atrophy. Torsion with infection by bacteria leads to true moist gangrene

# The Lettsomian Lectures

ON

# CERTAIN DISEASES OF THE BLOOD-VESSELS.

*Delivered before the Medical Society of London*

BY A. PEARCE GOULD, M.S. LOND.,
F.R.C.S. ENG.,
SURGEON TO MIDDLESEX HOSPITAL

## LECTURE I.[1]

*Delivered on Feb 17th*

### VARICOSE VEINS. THEIR NATURE AND IMPORTANCE, AND THE VALUE OF TRENDELENBURG'S OPERATION.

MR. PRESIDENT AND GENTLEMEN,—My first and most agreeable duty is to thank the council of this society for the honour which they have conferred upon me in appointing me to deliver the Lettsomian lectures. Would that I could make a worthier response. I can only ask that the kindness which prompted the invitation may be extended to me now as I offer a contribution which I know is not worthy either of this society or of my predecessors in this office

I believe that it is generally desired that the subjects of the Lettsomian lectures shall be as practical as possible—that they shall deal with affections which perhaps often come under the notice of the Fellows of the society, and in that belief I propose to devote this lecture to a consideration of certain points in connexion with varicose veins. I will not attempt to give you an exhaustive account of this affection or an analysis of the views that have been held in regard to the causes, the consequences, or the best treatment of varix. I will limit myself to a brief discussion of those features of the disease which have chiefly impressed themselves upon me, and will then submit to you the results of a somewhat extended trial of the particular method of treatment which was first employed by Trendelenburg in 1891 and which bears his name

### THE NATURE OF VARICOSE VEINS.

Two views of the nature of varicose veins are commonly held to-day. One regards them as the result of the yielding of the veins to an increased intravenous pressure due to an obstruction to the flow of blood up to and through the heart In support of this much can be said. It may be pointed out that varix is met with most often in the veins of the lower limbs and left spermatic cord and in those veins which are least well supported externally, the subcutaneous veins—that many of the subjects of them are following occupations which necessitate long standing or walking, or are suffering, or have suffered, from some obvious cause of venous pressure, such as the enlarged uterus of pregnancy. The relief that is sometimes afforded by external support to the veins is another fact that may be adduced in support of this theory. According to the other view varicose veins are to be regarded rather as venous overgrowths, a superabundant development of venous tissue—venous angeioma. In trying to decide between these two views the following facts and considerations have led me to reject the obstruction theory.

*The age at which varices are first noticed.*—In the great majority of cases varicose veins make their appearance before the growth of the individual is complete. They are one of the diseases of immature development Out of 50 consecutive cases of varicose veins of the lower limbs collected for another purpose, but in which this point was noted, I found that 41 patients observed their varices before the age of 25 years and only nine after that age. When we remember how unobservant patients, especially hospital patients, are of the date of onset of painless affections and how constantly we have to discount their statements on this point, we may be sure that these figures represent less than the truth Among the 41 cases, the age at which the varices were first noticed were given as follows:—

| | |
|---|---|
| 1 at 8 years. | 2 at 18 years. |
| 1 ,, 11 ,, | 3 ,, 19 ,, |
| 1 ,, 13 ,, | 4 ,, 20 ,, |
| 1 ,, 14 ,, | 1 ,, 21 ,, |
| 2 ,, 15 ,, | 5 ,, 22 ,, |
| 7 ,, 16 ,, | 2 ,, 23 ,, |
| 3 ,, 17 ,, | 6 ,, 24 ,, |

One patient said that she had had the enlarged veins "since she was a girl," and another said that "the veins had been enlarged as long as she could remember."

It is quite certain that puberty and adolescence are not the period of life in which venous obstruction predominates, nor are they the time of life at which strain is liable to tell upon the integrity of the vessel walls.

*The general condition of the tissues of the subjects of varix.* I am sure that we must all have been struck with the general condition of good, even robust, health of the large majority of patients when varix is first discovered. How often it happens that the disease is only discovered when a typically healthy youth presents himself for acceptance in some branch of His Majesty's service.

*The conspicuous absence in cases of varix of the usual symptoms and consequences of venous obstruction*—This is another noteworthy point. We have many opportunities of seeing the effects of venous obstruction—œdema, lividity, and impairment of function In the great majority of cases of varix these symptoms are all absent. I have seen the most extreme degree of varicose veins which had persisted for many years without any, even the slightest, alteration of the skin or subcutaneous tissue—neither œdema, induration, nor any loss of function—and such must be the experience of you all But when we come to study other cases in which there is undoubted venous obstruction, how grave and striking these symptoms always are Even in such a simple case as a slightly ill-applied bandage—just a very little impeding the venous return—how immediate is the discomfort, how quickly the whole member below becomes obviously congested and how rapidly œdema supervenes And in the graver cases of valvular derangement of the remain much more sensitive than it was before the affection of the gland came on, and in certain instances a form of neuralgia may distress the patient for a long period of time unless the organ is removed Sometimes the retained testis affected with fibrosis may be considerably enlarged so as to simulate a new growth In these cases there have, as a rule, been many attacks of inflammation and the fibrous stroma and covering of the gland are all much increased in thickness Adhesions of the testis to the inner surface of the tunica vaginalis may result which will usually lead to a greater fixation of the organ than heretofore

---

[1] Lectures II. and III. will be delivered on March 3rd and 17th respectively.

Although it is undoubted that atrophy may, and often does, follow upon inflammation of the arrested testis, yet it is open to considerable uncertainty as to whether malignant disease is ever attributable to the same lesion Irritation and inflammation of the imperfectly descended gland may possibly in some rare cases initiate such changes in the testicular tissues, so far as its embryonic constituents are concerned, as to bring about the incidence of a new growth In a few instances where the testis has been found in the inguinal canal and has been the seat of inflammation peritonitis has been set up within the abdomen, owing to the fact of the communication between the processus vaginalis and the general cavity of the peritoneum

*Inflammation due to the extension of disease from the urethra* —Occasionally the passage of a catheter along the urethra has caused a septic urethritis which has later extended along the vas deferens of an arrested testis and produced an epididymo orchitis There are also some records of cases where a prostatitis other than one dependent upon gonorrhœa has been followed by inflammation in the retained gland But an affection of the epididymis and afterwards of the testicle itself from the passage of the gonococcus along the urethra to the prostate, through the common ejaculatory duct, past the vesicle, up the vas and down to the globus minor of the epididymis, is the most usual form of disease of the arrested testis caused by an extension of inflammation from the urethra Here, again, suppuration is rare, for if the urethral lesion is a double infection of the gonococcus, accompanied by the staphylococcus pyogenes, the latter is but rarely so resistant as to be able to travel alive as far as the commencement of the vas deferens

Gonorrhœal inflammation of the arrested organ is apt to be more severe than that occurring in a testis which is in the scrotum Where the testis remains within the abdomen peritonitis may supervene owing to the extension of the gonorrhœal inflammation to the adjacent serous membrane In a few cases in which the body of the testis has been fixed in the inguinal canal and the epididymis has passed into the scrotum together with the vas, a gonorrhœal infection has occasioned a swelling and tenderness in the latter region, and perhaps no discomfort above Poupart's ligament A fact which is worthy of attention is that it is by no means infrequent to find a specific epididymitis of the fully descended organ while its arrested fellow escapes sharing in the inflammation As in the traumatic inflammation of the imperfectly descended testis atrophy may occur, so it may follow a gonorrhœal infection of the same, and is probably more generally the termination of the lesion than it is when the organ is normally placed

An orchitis of an arrested testis may occur during an attack of acute parotitis In such instances, as is the case in the similar affection of the fully descended organ, the inflammation is prone to be very severe and for the time being alarming Atrophy subsequently is, moreover, very common as a sequela

A tuberculous infection of the tissues of a testis which has not reached the scrotum is a very rare condition, and this may possibly be accounted for by the fact that the undescended organ is often so poorly developed that its blood-vessels are neither so abundant nor so large as are those of the normal gland and therefore tubercle bacilli are not so readily brought to the part Further, should there be primary tuberculous deposits in other portions of the genito urinary tract, it is not so likely that they should pass to the testis along the vas if this structure has a very narrow lumen A secondary infection of the peritoneum, particularly if the testis is retained within the abdominal cavity, is likely to be set up

Syphilitic infection of the arrested testis, whether secondary or tertiary, is also extremely rare, very much rarer than it is in the normally placed organ, and its rarity is all the more remarkable seeing how commonly traumatism, often the precursor of a syphilitic inflammation, affects the retained gland.

*Torsion of the cord of an imperfectly descended testis* —Torsion of the spermatic cord may occur in connexion with the fully descended or imperfectly descended testis Nearly 50 per cent , however, of the recorded cases are those in which the testis has been arrested, and in the other half there is usually some abnormality of the testis or its annexa Almost all viscera within the abdomen which possess pedicles are at times the seat of axial rotation, and many tumours which form within the abdomen are also liable to have their pedicles twisted There are a number of predisposing causes which possibly act in bringing about torsion Imperfect descent of the testis, an abnormally long mesorchium, a practical absence of a mesorchium, action of the gubernaculum testis, a congenital twist of the cord, a roomy tunica vaginalis, and a flattened condition of the imperfectly descended organ, are all factors predisposing to torsion There are two important peculiarities that may be present in the testis which has not reached its proper habitat These are an abnormally long mesorchium, and the existence of two cords supporting the testis, the one consisting of the vessels, the other of the vas deferens Frequently the two conditions are found at one and the same time The reason of this anatomical arrangement is not far to seek The body of the testis has its own blood-supply, and these vessels lie in the plica vascularis, which will then form one cord or part of the mesorchium, while the epididymis and the vas have an altogether separate origin, and therefore a different blood supply, and they consequently tend in some cases to form a distinct cord, which may become itself the site of torsion It thus comes about that the imperfectly descended testis is less firmly attached than is the normally situated one, and there is a liability, if any exciting cause occur, for axial rotation to take place Probably an absence of a mesorchium is a condition which is seldom, if ever, present It is extremely doubtful whether the gubernaculum can ever exercise any influence in bringing about torsion It has been suggested that as the outcome of intra uterine peritonitis a congenital twist may be given to the testis in its descent, and that later this may be aggravated by an exciting cause of torsion being added to it A roomy tunica vaginalis would certainly give more space for the occurrence of a twist To sum up, it is probable that partial descent with a freely moveable testis is the chief predisposing cause of torsion of the spermatic cord

As exciting causes may be mentioned a muscular effort, a mechanical twist, the action of the cremaster, the application of a truss, attempts at the reduction of a hernia by taxis, and possibly the enlargement of the organ at the approach of puberty Others have thought that a primary thrombosis of the vessels of the pampiniform plexus exists, and that torsion is merely secondary to this A sudden muscular effort with the testis lying in the inguinal canal is the history of many cases of torsion As soon as the vessels of the cord undergo a rotation around their longitudinal axis the circulation of blood within them is seriously interfered with The onset of torsion more markedly affects the thinner walled veins than the artery, with the result that while the blood is pumped in through the latter it cannot properly return through the former The consequence of this is a rapid and extreme turgescence of the veins of the pampiniform plexus and great congestion of the whole of the parts from which they derive their blood It is this over full state of the vessels that leads to the agonising pain from which the patient suffers Soon the testis becomes greatly increased in size, often to twice, or even thrice, its original magnitude Occasionally it is only the epididymis that is enlarged, the body of the testis remaining almost its usual size This will be the result of a twist only of that cord which carries the vessels of the epididymis and vas

If the congested testis is exposed by an incision it will be found to be bluish black in colour, not unlike a ripe purple plum, and somewhat like very deeply congested gut (Fig 8 ) This discolourisation may in some instances be visible even through the skin A certain amount of fluid, usually blood-stained, may transude the distended vessels into the cavity of the tunica vaginalis Sometimes the vessels actually give way under the pressure to which they are subjected, and pure blood is thereby extravasated It is interesting to note that there may be a comparatively early invasion of the congested tissues by bacteria, both cocci and bacilli, but possibly only in the cases in which an accompanying hernia the scar, and seems to enter the stump of the saphena vein where it opens into the femoral vein.

Another case (No. 8 in the table of cases) occurred in the person of a member of our profession.

CASE 3.—The patient himself thus describes the case: "At the age of 19—in 1894—I had tortuous veins on the inner side and back of both calves and a prominent internal saphena vein in each thigh in which could be felt a thrill on coughing. At the left saphenous opening was a slight bulging of the vein. Operation in 1894 by Mr. X—excision of a portion of the internal saphena vein in the upper part f the thigh, but I think about an inch or more was left between the ligature and the saphenous opening. This relieved me and the aching pains I used to get went away. Then the veins began to get big again in the calf and in the site of the operation in the left thigh a large mass of veins began to grow which were bigger than I had had before anywhere. These Mr. X excised for me in 1896, at the same time excising most of the tortuous or prominent veins in the calf of each leg. For about three years I kept very free from any discomfort from my veins, but in the summer of 1899 I began to feel them and I had sudden twinges of pain in them when standing in the wards and theatre. They (the varices) had then recurred in the left calf, the right remaining well." This gentleman then consulted me and I found the scar in the upper part of the left thigh occupied by quite a close congeries of large veins which communicated freely with the two ends of the saphena vein. I operated in October, 1899, and removed these veins and tied off the upper end of the saphena vein as close as possible to the common femoral trunk. He adds in the letter which I have quoted from above, "I have been very comfortable since and have no pain in them now." In this case, then, new veins of considerable size were seen to develop twice over in a scar in the thigh, and each time these veins acted as a free channel of communication between the divided ends of the internal saphena trunk.

I think that such cases may be fairly quoted as demonstrating the occasional development in the adult of what may be classed as "venous angeioma." Admitting the possibility of the development of a venous angeioma in the adult, what evidence is there to support the view that varix is a form of venous angeioma?

1. In the first place I would point to the fact that we occasionally meet with cases in which we have a *combination of undoubted venous nævus and varix*, and other cases in which the condition might almost equally well be designated by either of these terms. Several years ago I showed to this society a young woman who presented a most remarkable appearance. The left half of her body from head to foot was the seat of a very extensive diffused angeioma—in great part it was a capillary nævus, part of it was rather of the character of a venous nævus, and yet other parts were indistinguishable from ordinary varix. This was a congenital malformation or error of development, but it suggested to me very powerfully the similarity of varix and venous angeioma. This month I had in the Middlesex Hospital a man with a large venous nævus of the scrotum which occupied the whole of the scrotal raphe and extended along the under surface of the sheath of the penis, and also back into the perineum. I excised this growth and in doing so exposed and removed in the subcutaneous scrotal tissues veins which I could not distinguish from ordinary varices. Further, this man had on the inner edge of his left buttock an area of subcutaneous fascia about two inches in diameter occupied by dilated veins or venous spaces, and on the lower part of the thigh and the leg of the same side were some quite unmistakeable varicose veins. Two or three weeks ago I saw a young woman on whom I had performed Trendelenburg's operation some time before. Her thigh presents a truly remarkable appearance. She is well nourished, with abundance of subcutaneous fat, and in this fat the varicose veins are so numerous that they give a blue tint to the whole limb, and I think that it is as reasonable to regard the condition as a very diffused nævus as it is to speak of it as a very extensive varix. Only this week I saw a patient, 50 years of age, who has what she calls a "wine-and-water mark" covering the upper two-thirds of the right leg and nearly the whole of the thigh, on the outer side extending up to the groin. The subcutaneous tissue is occupied by a close network of dilated veins which project on the surface when very large and give to the whole part a blue colour. The veins are indistinguishable from ordinary varices, but the condition is peculiar in having been present since birth. Many years ago I saw among my out-patients at the Westminster Hospital an old man of 80 years of age whose right leg from knee to ankle was closely covered by a congeries of large veins, many of them of the size of a woman's little finger, which were so numerous that nowhere could a shilling have been placed on the leg without resting on one of these veins. The old man told us that his leg had been like that for 60 years and had never given him any trouble; he came to the hospital for quite another affection. More common and, I think, more striking than these cases, are those others of varix involving the minute veins of the skin. We often see a kind of splash of this condition just above the knee, sometimes superficial to a dilated saphena vein. How exactly it resembles the mildest form of nævus of the skin, or the edge of a nævus undergoing spontaneous cure! Indeed, I think that I have seen every grade between the undoubted congenital venous angeioma and the most uncompromising acquired varicose vein, and this fact has certainly borne in upon me the essential oneness of the two conditions.

2. Notice again the *capricious irregular distribution of varices.* In one case it is the whole saphena vein from groin to instep that is enlarged, no one of its tributaries being involved. In another case it is merely a short section of this vein that is varicose. In a third case the saphena trunk and several of its main tributaries are dilated. In a fourth case the disease involves only some second- or third-rate tributary and leaves the main vein unaffected, or a large varix may be found lying over the normal vein. Large varices are not uncommonly seen in situations where no vein of any size is normally present—e.g., across the front of the patella. Lastly, in a few cases the enlargement appears to involve an enormous number of veins in the whole subcutaneous tissue of the leg or thigh almost uniformly, although the trunks may not be specially enlarged—and yet there is no sign of any impairment in the venous drainage of the tissues. This extreme irregularity and variation in the seat and extent of the affection seem to me to mark it out as an over-development of the venous tissue—errors of development often showing such caprice.

3. *The early age at which varix usually develops* is another interesting fact bearing upon its nature and eminently consistent with the developmental theory.

4. Further evidence pointing to the same conclusion lies in the fact that *varicose veins seem to be distinctly hereditary.* It is very difficult to express this with anything like mathematical accuracy, as a large proportion of patients are unable to give any information about varices in other members of their family. It is not an obvious deformity or defect that cannot be hid—a sister is not likely to know of a brother's varicocele or a brother of a sister's varix unless it causes serious inconvenience. But in spite of this difficulty in getting anything like full family histories on the point it is surprising how often patients tell us of other members of their family who have varicose veins too. The young medical man whose letter I have just quoted mentions in that letter that his father and one of his two brothers have varicose veins. Two days ago I operated upon the daughter of a medical man for varix in each lower limb whose father also suffers from varicose veins. A gentleman whom I have seen on two or three occasions for very large varicose veins which he has had all his adult life and which have in no way interfered with a most active life, including such sport as deer-stalking, mentioned on his last visit that his eldest son—a youth in his teens—was just developing varices in his thighs and legs. I might, indeed, quote from my note-book case after case illustrating the same fact. The very last case of varicose veins I saw was that of a young man who told me that his maternal grandmother, his father, and his two brothers had varicose veins in the legs—he did not know about his sisters. Out of 102 cases of varix of the limbs collected for another purpose I find that the disease was known by 52 patients to be present in some member or members of their families—more than 50 per cent. In the table of cases of Trendelenburg's operation I have put this detail in where I could, and if you will run your eye over the table, I think you cannot fail to be struck by the frequency with which the entry occurs. We know nothing of the real nature of hereditary influence, but we notice that it seems to show itself more often in errors of development, whether by way of excess, or defect, or variation, than in any other way.

5. *The striking innocuousness of varicose veins* in the great

heart, or the growth of tumours or plugging of a main vein where the obstruction, even if it is slow and gradual in onset, is yet persistent, we are never at a loss to notice the grave effects upon the tissues when they are imperfectly drained of their venous blood

The varicose veins that we know and are now thinking of are enlarged cutaneous and subcutaneous veins—parts of a very abundant even superabundant, system of veins—and we are all aware of the fact that many of these veins can be removed or plugged with clot without any injurious effect upon the circulation of the limb, so many and free are the alternative channels which nature has provided for the return of the blood to the heart But this fact has no bearing upon the point which which we are now discussing, for the theory of obstruction always supposes that the obstacle to the free return of blood is one that acts upon the deep main veins and through them upon all the radicles communicating with them And I submit to you that in uncomplicated cases of varicose veins there is, in the very great majority of cases, no evidence of general venous obstruction in the affected part at the onset of the disease—evidence which is not obscure or difficult to recognise and appreciate but which stares us in the face in all cases of undoubted obstruction in deep veins It is an error to accept the enlargement of superficial veins as evidence of obstruction in the main channels into which they open The evidence of this obstruction is to be sought in general venous engorgement of the part, followed by œdema and its consequences

*The result of excision of varicose veins and also of ligature of the main superficial vein into which they empty their contents* —If the cause of a given varix is some deep obstruction it is clear that to excise the varix is the most irrational procedure and could in no case be fraught with good Or to cause a further obstruction to the venous return by a ligature of the main superficial vein through which the varix is emptying its blood must of course, exaggerate the evil and cannot possibly mend matters And yet there is no clinical fact better attested than the success of both of these measures I think that we have here a decisive refutation of the obstruction theory of varicose veins, and if anything could add to its force it would be the disastrous results that are obtained when an incautious surgeon operates upon veins which are enlarged as the result of obvious undoubted central obstruction—a femoral thrombosis for instance

*The influence of pregnancy* —Women often tell us that they had not been troubled by enlarged veins until during or after pregnancy It is, indeed, commonly held that pregnancy plays an important role in the etiology of varix Before we can rightly judge of its importance, however, there are several other facts to be borne in mind At the outset we must carefully distinguish between conditions causing varix and conditions leading to pain in varix Over and over again observant women have told me that they had noticed their enlarged veins in early life before marriage, but that they had *never been troubled by them until they were pregnant* If one is careful to press this distinction it soon becomes obvious that while pregnancy is often a cause of pain in varix it is not very often the cause of varix It is also noteworthy that it is not uncommon for a woman to say that her veins were only noticed to be enlarged when she "got up after her confinement" or even later when she "weaned the baby" While admitting of course that the pregnant uterus may be and often is a cause of pressure upon the common iliac veins or vena cava and so acts as an impediment to the venous circulation in the lower limbs, it is to be remembered that, quite apart from any pressure-effects, pregnancy produces in some women quite remarkable vaso motor disturbances, and it is an error to conclude that all venous engorgements must of necessity result from the mechanical pressure of the enlarged uterus In this connexion it is important to notice that many women complain of pain in their varicose veins at the very commencement of pregnancy before the uterus has risen high enough to press upon either common iliac vein and these women not infrequently tell us that those pains abate in the later months of pregnancy when the pressure upon the veins must be at its maximum I believe too, that it is a fact that large ovarian and uterine tumours are less often attended with troublesome varices of the lower limbs than in pregnancy—a fact (if it be a fact) which surely points to some other factor as well as pressure upon the main veins coming into play in the enlarged and painful varices of pregnancy

*The sex incidence of varix* —But if we look at the influence of pregnancy from another point of view altogether we shall, I think, see still further reason to believe that its influence in causing varicose veins has been over estimated When we consider the frequency of pregnancy in the female sex and the great abdominal distension and pressure that it causes in the later months I think that we shall be bound to admit that there is no condition or even group of conditions in the male sex that can possibly equal the effects of pregnancy in embarrassing the venous circulation of the lower limbs And therefore on the obstruction theory we should expect to find varices of the lower extremities much more common in women than in men But what are the facts? Sir William Bennett's statistics show the incidence to be about equal in the two sexes I have gone over my notes of all the cases that I have seen in private practice and to them I have added all the cases in my hospital practice for the last six years, excluding cases of varicocele—they number 245 Of these patients 153 were men and 92 were women, a proportion of rather more than three males to two females At the hospital I have more female than male beds, and I am unaware of any reason why my experience of the frequency of this affection in the two sexes should not represent the fact If so I think that we must conclude from this survey of the sex incidence of the disease that pregnancy cannot play an important part in causing varix If I had included all my cases of varicocele during the same period the sex-incidence would, of course, have shown a much greater preponderance in men

But if we reject this first theory what grounds are there for adopting the other—the view that varicose veins are venous overgrowths—venous angeioma? Before answering that question it may be well to ask another Is there any evidence that a growth of veins—a highly specialised structure—ever occurs in adolescent or adult life? We have all seen cases of the development of arterial angeioma or aneurysm by anastomosis, and that forms a fair analogy, and we are very familiar with venous angeioma as a congenital growth which if neglected may continue to grow after birth and assume even large proportions We cannot fail too, to be impressed with the apparent superabundance of veins in the normal condition Nature appears to be very prodigal in the supply of veins, and nowhere more so than in the primary veins of the lower limbs and their tributaries Large numbers of veins may be obliterated without any interference with the capillary outflow These facts would prepare us to observe a growth of veins in adults, and I think cases like the following are conclusive evidence that such a growth does occur

CASE 1 —In October 1895 an agricultural labourer, 46 years of age was admitted to hospital under my care suffering from extensive varices in the lower third of the left thigh and in the left leg These caused him so much pain that he was unable to continue at his work even although he wore an elastic stocking or a rubber bandage I excised about one and a half inches of the internal saphena vein above the highest varix and a little below the middle of the thigh In a fortnight the man returned to his work and for two years he was able to work in perfect comfort the varices having in the meantime shrunk and being always lax At the end of two years he began to complain of the old pain and I found that the varices were fuller and tenser On looking at the thigh I found that the saphena vein was varicose above the scar of my operation and close alongside the scar a large vein could be plainly seen and felt passing from the saphena vein above the ligature to the vein below and this accounted for the return of the man's pain, &c

I have seen other similar cases where after I have cut out a piece of the saphena vein in the middle of the thigh, either a single large vein or a number of veins have developed in the scar and have formed a new and free communication between the divided and separated ends of the saphena vein The other day, when examining some of my old hospital patients on whom I had performed Trendelenburg's operation—excision of the upper end of the internal saphena vein—I came upon such a case (No 16 in the table of cases)

CASE 2 —The patient was a man, 41 years of age, upon whom I operated in July, 1900 He had then rather large varices in the left leg and an ulcer over the inner malleolus. He left the hospital with the operation wound and the ulcer soundly healed There is now a large varix in his groin which communicates with the upper end of the lower part of the divided saphena vein, passes round the outer edge of

TABLE OF CASES OF VARICOSE VEINS SHOWING THE RESULT OF TRENDELENBURG'S OPERATION—(*Continued*).

| o. | Age. | Sex. | Date of operation. | Condition before operation. | Result. |
|---|---|---|---|---|---|
| 7 | 35 | M. | July, 1900. | Veins enlarged for 16 years; they had been painful for the last few months. There was some eczema on the left leg. The internal saphena was large and prominent on both sides. There was great dilatation of the vein at the saphena opening on the left side. His father had varicose veins. | Seen January, 1902. He experienced marked relief for a year afterwards. There was no pain now in the right leg; the left leg pained him below the knee. *The vein in the thigh was very small; below the* knee were two varicosities much smaller than before. |
| 18 | 25 | F. | August, 1900. | Veins swollen and painful for the last three years. The veins were enlarged on the front of the right leg and the inner side of the left thigh. Other members of the family had varicose veins. | Letter, January, 1902: "My legs are very much better. The vein in the right leg is still a little swollen and rather painful periodically, but generally speaking I do not find anything of it, and it is nothing like it was before the operation." The veins in the left thigh cause no trouble. |
| 19 | 37 | M. | August, 1900. | Varicose veins in the left leg "since a child"; nine years before operation a vein burst. In 1889 at the Italian Hospital three varices and a thrombus were excised. Lately the veins had been very painful. There were large blue swellings beneath the scars of former operations. | Seen January, 1902. A very good result. The veins were shrunk and lax. He said that he "occasionally has a pricking pain if he stands very much." |
| 20 | 27 | F. | August, 1900. | Was a nurse in hospital. Had varicose veins on both sides. | Letter, January, 1902: "Since the operation I have had no trouble with my legs; they do not swell, are not painful, and I can follow my occupation as a nurse with no discomfort, though the veins are still slightly enlarged." |
| 21 | 65 | F. | October, 1900. | Varicose veins "noticed when a girl." Had an ulcer occupying the lower third of the front of the left leg. There were numerous varices above it. | Letter, January, 1902: "My leg is quite well," no pain or swelling. The veins are their natural size. "I can do all my house work and take walks without discomfort." |
| 22 | 19 | M. | November, 1900. | Varicose veins noticed at eight years of age. Pain and the varicose condition had been getting worse during the last two years. The enlarged veins were situated on the back and outer side of the left calf. His mother had varicose veins. | Seen January, 1902. A very good result. The large varix just below the knee had disappeared; those over the inner side of the calf were much smaller and soft. "Never feels anything of it." |
| 23 | 35 | F. | November, 1900. | Had great irritation in the legs for the last five years. For the last two years had to rest repeatedly at work on account of pain. Large tortuous varices in both thighs and legs. Her mother had varicose veins. | Seen January, 1902. No pain in the limbs; was able to do her work better. Up to the time of operation the veins were enlarging; since then there had been no enlargement. There were numerous varices in both thighs and legs, but much less tense than before. |
| 24 | 39 | M. | January, 1901. | The patient was rejected for the navy at 16 years of age on account of varicose veins. In October, 1896, a vein burst and an ulcer followed. Since then two others had appeared. He had dull aching in both legs after any exertion. He had varices in both legs and thighs. His mother had varicose veins. | Seen January, 1902. No varices in the thighs; those in the legs were smaller and quite lax; he experienced no trouble from them. |
| 25 | 28 | F. | January, 1901. | Had varices both sides for eight years. There was increasing pain in the right knee and thigh for the last six weeks. The internal saphena in the right leg and thigh and in the left leg was enlarged. Her mother had varicose veins. | Seen January, 1902. The veins were much smaller. |
| 26 | 26 | F. | January, 1901. | Veins noticed to enlarge eight years previously during her first pregnancy. On the left leg were two small ulcers. Above the left knee there was a sacculus on the internal saphena vein of the size of a nut. The vein was enlarged down to two inches below the knee. Her mother had varicose veins. | Seen January, 1902. Scars of ulcers were quite sound. "No pain at all in the leg now." She felt "much better for the operation." |
| 27 | 38 | F. | February, 1901. | In March, 1896, the right internal saphena vein was tied above the knee; there was great relief for two years, then a return of the varices in both legs "*controlled*" by pressure on the internal saphena vein. | Seen January, 1902. "Left leg is always in pain. Right leg aches terribly at times; just the same as before." On the right leg numerous varices had developed in the scar and the varices below were as bad as ever. In the left leg the veins had shrunk and the pain complained of was not due to the veins; it was bad when she rested. |
| 28 | 40 | F. | February, 1901. | The veins were noticed 18 years previously during her first pregnancy; they were relieved after labour, but enlarged during each pregnancy. 12 months ago an ulcer appeared on the left leg. For the last 12 months pain day and night had been very severe. The internal saphena veins of the thighs and legs were varicose, also the veins of the feet. Her mother and two brothers had varicose veins. | Seen January, 1902. "No trouble since the operation." Ulcer soundly healed; the veins are smaller. |
| 29 | 18 | M. | February, 1901. | Enlarged veins were noticed for four months. He came for treatment on occount of the pain. The left internal saphena was enlarged in the thigh and leg. | Seen January, 1902. *Now no pain in the left leg,* the one operated on. Complained of pain in the right internal saphena vein which had not been operated on. |
| 30 | 35 | M. | April, 1901. | Had great pain for several weeks before the operation, so that he could not stand upright. An ulcer had existed for six weeks. The left internal saphena was enlarged in whole length above the ulcer. His mother and sister had varicose veins. | Seen January, 1902. Veins were a little smaller; there was no pain. |
| 31 | 25 | F. | April, 1901. | The whole leg below the knee was thickly studded with varices giving it a bluish look. Her mother had had varicose veins. | Seen January, 1902. She did not think there was much difference since the operation. |
| 32 | 27 | F. | April, 1901. | Noticed veins for 10 years. Got rapidly worse during the last three months. There were groups of varices on the inner side of the knee, joining others on the outer side of the leg. There was another group on the inner and posterior aspect of the calf and inner side of the ankle. | Letter, January, 1902: "No benefit from operation." "The veins swell as much as they did before directly I stand on my legs and also are very painful at times." |
| 33 | 17 | F. | May, 1901. | Varicose veins for two years. The leg was painful both on standing and sitting. The internal saphena was enlarged in the right thigh and both legs. | Seen January, 1902. The veins were quite small; there was no œdema or other complication. She complained of "pain and shaking in the legs"—a neurosis. |

TABLE OF CASES OF VARICOSE VEINS SHOWING THE RESULT OF TRENDELENBURG'S OPERATION

| No | Age | Sex | Date of operation | Condition before operation | Result |
|---|---|---|---|---|---|
| 1 | 31 | F | March 1899 | Internal saphena vein was tied in the middle of the thigh on each side in 1896, after a period of relief the pains had recurred and the veins had enlarged again Now the veins were tied in the groin | Letter, January 1902: "Since the last operation the veins have given me little pain My legs have not swollen much or prevented my doing a fair share of domestic duties" |
| 2 | 18 | M | March 1899 | Exceedingly large varices below the right knee continuous dull heavy pain in them One brother had varicose veins | Seen January, 1902. The veins were much smaller, there was no discomfort except a slight pain if he over-exerted himself There was no new varix |
| 3 | 37 | F | May, 1899 | The veins were large but not painful one burst and a great deal of blood was lost, and this led the patient to seek advice Her mother had varicose veins | Seen January, 1902 The veins were much smaller, they caused no trouble at all |
| 4 | 29 | F | May, 1899 | The patient had varicose veins in both legs for 10 years, they ached on walking about Three sisters had varicose veins | Letter, January, 1902 "The varicose veins are decidedly better, one leg is quite cured, but the other swells a little at times, but is seldom painful" |
| 5 | 28 | F | June 1899 | Varices in both legs and above the left knee The patient could remember the varicose veins since the age of 11 years, they had not altered much up to the time of the operation One brother had been operated on for varicose veins | Seen, January, 1902 "The operation had done her decided good she could walk much better, the legs were painful if she stood for two or three hours, but not so much as before |
| 6 | 26 | F | October, 1899 | Bunch of veins just below the knee, there were several smaller ones lower down, there was pain on standing | Letter, January, 1902 "Has had no pain or discomfort since the operation |
| 7 | 20 | M | October 1899 and March, 1901 | The patient had had varicose veins for four or five years, they were very painful and ached very much after a hard day's work The right internal saphena vein was tied in 1899, the left internal saphena vein and the right external saphena vein were tried in 1901 His mother had varicose veins | Seen January, 1902 The operation had done great good, the veins were cured He was employed at a large city warehouse and had no pain or discomfort |
| 8 | 24 | M | October, 1899 | Saphena vein in the thigh prominent from the groin to the knee, bulging at the saphenous opening, tortuous varices over each calf Two previous operations Recurrence of varix in the left calf with pain on standing His father and one brother had varicose veins | Letter January, 1902 "Quite free from any discomfort, veins hardly visible when cool, after long standing or getting hot they show up |
| 9 | 21 | F | November, 1899 | Noticed veins seven years previously Had a good deal of pain which was getting worse Both internal saphena veins were dilated and slightly tortuous One sister had varicose veins | Seen Nov 20th, 1900 Left internal saphena vein above the knee was large and varicose veins below knee quite small; no aching On the right side the veins had diminished in size considerably since operation, a little aching pain after prolonged standing |
| 10 | 28 | F | November, 1899 | Very numerous varices scattered generally over both thighs and legs, giving the limbs quite a bluish colour Subject to frequent attacks of thrombosis—as often as every other month Her father had varicose veins | Seen January, 1902 Since the operation she had had a slight thrombosis each autumn, "very slight to what it used to be |
| 11 | 27 | M | November 1899 | Extreme condition of varix in the right thigh and leg slight on the left side His father had varicose veins | Seen January, 1902 The right leg was quite well, the old varices could be felt, shrunken, soft and lax The left leg was worse, there was a varix at the back of the calf opening into the external saphena vein which ought to have been tied |
| 12 | 33 | M | May, 1900 | Veins on the inner side of the thigh and leg were very swollen and tender Excision of varices was performed at St Thomas's Hospital at 19 years of age, others formed in the leg and thigh, thrombosis occurred in the thigh His mother and one brother had varicose veins | Seen January, 1902 Had no trouble in the legs after the operation, was passed for military service in South Africa and was quite well there till September, 1901 when he suffered from a saddle-gall |
| 13 | 25 | F | June 1900 | Noticed vein three years A year previously the leg became much inflamed and very painful Large vein ran from the knee to the ankle One sister had varicose veins | Letter January, 1902 "Veins are quite the natural size and do not swell I have not had any pain or discomfort since the operation |
| 14 | 32 | F | June, 1900 | Pain from enlarged veins in both legs for three years, lately much worse There was some eczema of both legs The veins of both legs were varicose The left saphena was enlarged above the knee | Letter, January, 1902 "Veins are now their natural size not swollen and are free from pain and I now follow my occupation without any discomfort whatever from them" |
| 15 | 27 | M | June 1900 | Both internal saphena veins were enlarged and very tortuous from the saphenous opening to the foot The patient had not had pain in them The enlargement started in the calf and had spread upwards | Letter January, 1902 "Veins of left leg are normal Those of my right leg have swollen slightly since the operation The veins are not painful and do not hinder me in my work" |
| 16 | 41 | M | July 1900 | Had pain from the veins for four years Had an ulcer above the internal malleolus for the last two years Was compelled to rest in bed occasionally for from two to three weeks at a time Internal saphena in its whole length was varicose Had large ulcer over the internal malleolus at the time of operation The skin round it was eczematous One brother had varicose veins | Seen January, 1902 Leg did not trouble him now in the least" There was no varix in the thigh; those in the leg were smaller The scar of healed ulcer was quite sound A considerable varix had developed below the operation scar and opened into the highest part of the internal saphena vein |

majority of cases, also, I submit, supports the same view of their nature. An extreme degree of varix persisting for many years is by no means incompatible with unimpaired function and structure of the parts draining into the enlarged veins, and the varicose veins themselves will often persist throughout life without undergoing any secondary or further changes. This *stability* of varicose veins is, I think, an important point We often find them persisting quite unaltered for many years, and they are certainly less troublesome in the later than in the earlier years of adult life. It seems to me that this fact is more compatible with the view that they are an exaggeration of a normal physiological structure than the result of a pathological process.

6. The last point I would mention is the *minute structure of a varicose vein.* I believe that all the normal constituents of a vein are found in a varix and are usually increased in amount. It is often stated that the thick walls of a varix—and they may be very thick—are composed almost entirely of fibrous tissue. I have examined a good many and that has not been my experience: an increase of the muscular tissue is as notable as the increase of fibrous tissue and endothelial hyperplasia is sometimes a marked feature.

These, then, are the reasons which seem to me to show that varices are essentially the result of an over-development of venous tissue closely allied to, if not identical with, angeioma.

But associated with this growth of venous tissue there is very usually a failure in the valve apparatus which allows of regurgitation of blood from the main deep veins into the superficial veins. Since reading Trendelenburg's paper I have investigated this point in every case of varix of the lower limbs that has come under my observation, and I have found that regurgitation into the superficial veins is an almost constant phenomenon. The observation is made thus. Having examined the patient in the standing position he is asked to lie down on his back and the limb to be tested is raised to the vertical and the varices are completely emptied by gentle centripetal pressure. The thumb or forefinger is now placed in the groin so as to compress the upper end of the internal saphena vein and the patient is told to rise. It will be found that almost without exception the varices will remain lax and almost empty so long as the compression is maintained upon the main vein above, but that they fill out at once from above when the compression is removed. The regurgitation of blood into the superficial veins is sometimes most striking and obvious—in other cases it is less free, but I have rarely failed to demonstrate it in any well-developed case of varix. In some instances I have found that it has occurred from the popliteal into the external saphena vein instead of, or as well as, from the common femoral vein into the internal saphena vein. In one case I found that the back flow occurred through a small vein passing up the thigh just internally to the line of the anterior iliac spine as well as into the internal saphena vein. This regurgitation is not a normal condition. At my request Dr. H. Campbell Thomson has made observations on this point in the post-mortem room at the Middlesex Hospital, and he has entirely failed to inject fluid from the external iliac vein into the internal saphena vein, owing to the efficiency of the valves at the mouth of the superficial vein. He has made for me some preparations showing these valves. There is a double valve at the mouth of the saphena, the cusps being very unequal in size; two inches lower down another pair of cusps is found, and so on down the vein In the normal state these valves are quite efficient. I am convinced that the connexion between insufficiency of these valves and varix is close and important, and I must confess that even after reading Trendelenburg's paper I was not prepared to find the regurgitation so nearly constant or so marked as it is.

Before passing on to speak of the treatment of varix, I should like to say just a word about the importance of the affection. I am certain that the public have a very exaggerated notion of the gravity of varicose veins and one comes across certain neurotic individuals whose life is made miserable by the constant anticipation of evils which never arise.

The effect of varices upon the nutrition of the part, whether the leg or the testicle, is, I believe, very small, if indeed it be at all perceptible. Certain I am that many persons carry about in their legs and thighs for many years very large and numerous varicose veins, unalleviated by any external pressure or support, without suffering in any way at all—the skin remains elastic and supple, the subcutaneous tissue is free from œdema or induration, and the surface is proof against eczema or ulcer. The troublesome ulcer of the lower third of the leg with thickened edges and unhealthy base—so slow in healing, often so painful—the ulcer that I think has been nicknamed "varicose"—certainly occurs in splendid perfection in limbs devoid of a single varix, and its cause must be sought for elsewhere than in the veins.

The most frequent ill-effect of varices is a sense of fulness or weight in the part which may amount to severe aching in the distended veins. It is brought on by prolonged standing or walking and comes on much sooner in hot climates. It occurs only in the upright position and is at once relieved and quickly removed by recumbency. Some patients complain of a pricking or starting pain in the part. Neither the extent, nor the seat, nor the degree of the varix affords a measure or explanation of the suffering attributed to it. Many patients with well-marked and even extensive varices are able to undergo considerable fatigue without discomfort, while others with apparently far less cause make grievous complaint. The most striking instance of this that I have seen was a nervous, ill-nourished man with a quite moderate development of varices in both legs. He described his sufferings from the veins as most severe and sufficient to make his life miserable, and he gravely assured me that often when attending meetings of boards of directors in the City he had to retire into an adjoining room and to stand on his head "to let the blood out of his legs." This is the only *frequent* ill-effect. Much less often we meet with thrombosis in a varix or started in one—and more rarely still a vein bursts or is ulcerated into and free venous hæmorrhage occurs. Where varicose veins do not trouble the patient he need rarely trouble about them. But a young woman with large varices is wise to have them treated before marriage and pregnancy, and young people of either sex should have them treated before going to live in a hot climate. Thrombosis I propose to speak of in a subsequent lecture.

### TRENDELENBURG'S OPERATION.

Believing that insufficiency of the valve at the opening of the internal saphena vein plays a great part in causing varix below, Trendelenburg in 1891 proposed to treat the disease by division of the upper end of this vein between two ligatures. The operation has been extensively practised, but I believe that there is a wide divergence of opinion as to its value. For the last six years I have treated almost every case of varix in the lower limbs that has required operation by Trendelenburg's method, and as my cases up to the end of 1901 numbered 120 I hope that my results, so far as I can describe them, may be of service in leading to a correct estimate of the value of this treatment. The operation has the great advantage of being a simple one, rarely requiring more than five minutes for its performance. Gas and oxygen are often the only anæsthetic needed. The saphena vein can readily be found by remembering that it lies a finger's-breadth to the inner side of the common femoral artery, the pulsation of which can easily be felt in the groin. I prefer to expose the vein by an oblique incision from one and a half to two inches long parallel with the fold of the groin and having its centre over the vein. The vein is found lying between the two layers of the superficial fascia, it is cleared and a double ligature is placed on it, one thread being tied as high up on the vein as possible, the other about two inches lower down, and the intervening portion of the vein is cut out. The wound is closed by a few points of suture and is sealed by a collodion dressing. The patient is able to get up, as a rule, on the eighth day and to leave the hospital two days later.

I published the results of my first 50 cases—so far as I was able to learn them—in THE LANCET in 1899.[2] I have prepared a table of the cases operated upon since that date, but I have included in it only those cases whose present condition I have myself seen or received a written report of. These are 50 in number. As far as possible I have recorded the patient's own words so that I may not even unconsciously colour the report

Two young patients—Nos. 31 and 32—are no better for the operation; all the others have experienced benefit. The results of the operation may be submitted to three tests: (1) its influence upon the patient's comfort; (2) its influence upon the veins themselves; and (3) its influence upon the liability to thrombosis.

---

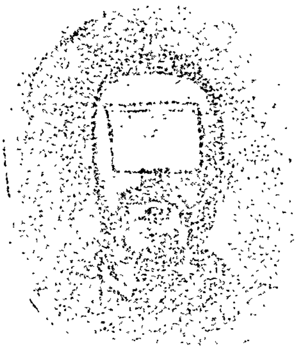
[2] THE LANCET, April 8th, 1899, p 941.

TABLE OF CASES OF VARICOSE VEINS SHOWING THE RESULT OF TRENDELENBURG'S OPERATION—(*Continued*)

| No | Age | Sex | Date of operation | Condition before operation | Result |
|---|---|---|---|---|---|
| 34 | 29 | M | May, 1901 | Started about five years previously The veins on the inner side of the right thigh and leg were much swollen and tortuous, also on the inner side of the left thigh His father, mother, and two brothers had varicose veins | Letter January, 1902 "The operation has been attended with perfect success Since about six weeks after the operation there has been no pain or swelling, the veins are reduced to their natural size, and I am able to attend to my usual occupation without the slightest inconvenience or discomfort" |
| 35 | 22 | M | May, 1901 | Painful on standing | Letter January, 1902 "The veins still swell The veins are not painful and I am able to follow my occupation without discomfort from them |
| 36 | 38 | F | June 1901 | The patient came to hospital on account of pain The veins had been enlarged for 22 years There were varices on the inner side of the left leg also on the inner side of the right leg and thigh and the outer side of the right foot Her father had varicose veins | Seen January 1902 Quite free from pain |
| 37 | 31 | F | June, 1901 | The veins were painful There was a large varix on the inner side of the left leg | Letter January, 1902 "I am able to get up and down stairs better than I have done for the last 10 years There is no pain The veins still swell |
| 38 | 26 | M | July, 1901 | The leg ached after standing, the patient was afraid of rupturing a vein when at work | Letter, January, 1902: "Legs quite well I still follow my usual occupation which is that of a coppersmith and necessitates a great strain on the legs The veins are their natural size and are perfectly smooth, and I feel no discomfort whatever from them |
| 39 | 17 | M | October, 1901 | Veins enlarging for one year Ached slightly after work Trendelenburg's operation was done on both sides and at the upper end of the short saphena of the right side | Seen January, 1902 The veins were smaller He had not felt any inconvenience in them since operation |
| 40 | 32 | F | October, 1901 | Varix at the upper end of the internal saphena vein ulcer on the right leg | Seen January, 1902 She had lost all pain The scar of ulcer was quite sound, there was no œdema |
| 41 | 22 | M | October, 1901 | The veins caused slight irritation at night | Seen January, 1902 The veins were much smaller He had no inconvenience from them |
| 42 | 39 | M | November, 1899 | A very neurotic man Varix was first noticed at 18 years of age and had been steadily increasing ever since The right internal saphena vein was varicose in the lower quarter of the thigh and below the knee In the left leg was a bunch of varices communicating with both the internal and external saphena veins and other varices lower down Both the internal and the left external saphena veins were tied | Seen May, 1900 All the varices were decidedly better He complained now of pain on standing which was relieved by raising the legs This pain started in the right buttock passed down the back of the thigh to the knee to the heel and on to the base of the fifth metatarsal bone There was tenderness on pressing over the great sciatic nerve |
| 43 | 41 | F. | February, 1900 | Varices in each leg which were only controlled when the external and internal saphena veins were compressed The patient had worn elastic stockings for years and even with them had great pain on standing and walking Felt "quite well down to her groins Both the internal and the external saphena veins were tied | Letter, February, 1902 "I have no pain, one leg is perfectly cured and the other just shows the vein I am often glad that I went through the operation |
| 44 | 59 | M | April, 1900 | Numerous large varices in the left leg involving the internal saphena vein and its branches, the main vein was enlarged up the lower half of the thigh and at the saphenous opening When the internal saphena vein was compressed two small varices in the calf partly filled out, when the external saphena vein was also compressed all the varices were kept empty Both the saphena veins were tied | Letter February, 1902: "I have never had a moment's trouble since my operation and my legs are in perfect condition |
| 45 | 53 | F | March 1900 | Many varices in the left leg and thigh which ached greatly when she stood Had had one attack of thrombosis | Letter February, 1902 "Veins are only slightly swollen No pain on standing or walking" |
| 46 | 30 | F | April, 1900 | The right internal saphena vein formed many tortuous loops up the leg from the foot to just above the knee There was aching pain Operation was advised in view of approaching marriage | Letter February, 1902 No pain or trouble Veins smaller Has had one child and one miscarriage No trouble during pregnancies |
| 47 | 39 | F | July, 1900 | Varices in the right thigh There were much aching and twitching pain on standing and walking | Seen February, 1902 The patient was very much better There was no pain now, she was able to do her work as a nurse without discomfort The veins were smaller |
| 48 | 44 | M | May 1901 | Many varices over the lower two thirds of the thighs and all down the legs to the ankles with prominent veins over each outer malleolus There was pain on long standing and on walking Both internal and external saphena veins were tied and the varix over each outer malleolus was excised | Seen February, 1902 There was much less pain—practically none The veins were smaller but were still visible |
| 49 | 29 | M | January, 1900 | Numerous varices in the right thigh and leg since 16 years of age The internal saphena vein was varicose below the middle of the thigh much so just below the knee there were several large veins all round the leg A large vein passed up the front of the thigh well to the outer side of the femoral vessels and appeared to enter the circumflex iliac vein Pressure on the internal saphena vein did not control the varices pressure on it and the vein to the outer side of the thigh did He had lately had several attacks of slight thrombosis Both veins were tied in the groin | Seen December, 1901 Was very much better He took active exercise—cycling golf shooting and hunting—without pain The internal saphena vein and tributaries had shrunk almost to normal size The outer vein on the thigh was not materially altered, it appeared to have a deep communication just above the middle of the thigh and through this it was filled by regurgitation |
| 50 | 38 | F | August 1901 | Moderate varices of the right internal saphena vein in the thigh and leg There were several dilated veins in the groin and the inner and upper part of the thigh She complained of a great deal of pain especially in the groin, which often unfitted her for her work | Seen February, 1902. She had lost her pain and was able to do hard work as a nurse without any discomfort—a thing that was impossible to her for years before The veins had many of them disappeared and all were much smaller |

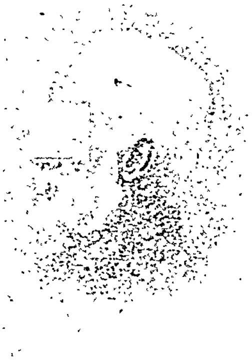
himself in the wards. He was less aggressive and he talked more freely and sensibly about incidents that had occurred in his past life. His sight was very good and his hearing tested with Galton's whistle was preternaturally sharp. His common sensation and other senses were normal. The heart and the lungs were unaffected and the blood-pressure was 130 millimetres (Hill and Barnard). The urine was normal. The history of his family obtained from his wife and himself was free from insanity. Born a Londoner, his father lived to the age of 78 years, and had not lost his hair, which was grey. His mother lived to the age of 76 years and had no grey hairs. His maternal grandfather died a very old man, older than did his father, and was said to have had no grey hairs. His maternal grandmother he could not remember. His paternal grandfather died at a good age, and his paternal grandmother was not grey when she died at the age of 78 years. He had one brother and two sisters; none of them had ever been in an asylum. His mother had five sisters and one brother. His father had one sister and two (? or three) brothers. None of the uncles or aunts were ever in an asylum. His four children (girls) were all well. None of the family had ever had gout or rheumatism. Reproductions of photographs of him are appended before and after the change in the hair. (Figs. 1, 2, and 3).

FIG. 1.



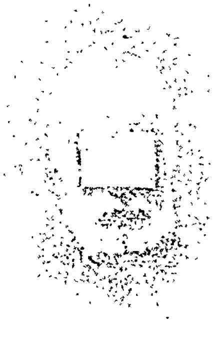
On admission.

FIG. 2.



After blanching.

FIG. 3



After blanching.

On microscopical examination the character of the hair as to number appeared to be normal and the following microscopical description given to me by Dr. J. S. Bolton from the pathological laboratory suggests that the condition was one of altered nutrition:—

> They are free from pigment and in their outer parts have an opaque and silvery appearance. The cuticle is extremely thin. The fibrous layer is atrophic and in the distal third of the hair is completely infiltrated with minute air lacunules; air is also present to a less extent in the middle third. The medullary portion is smaller and more varicose than usual. The bulbs are small and atrophic and are almost entirely free from adherent root-sheath.

REMARKS.

It is well known that certain coloured and certain textured hair accompanies and indicates certain temperaments and dispositions. This statement applies to individuals as well as to races. In Galton's observations,[2] taken from the report of the Anthropometric Committee of the British Association in 1880, the diagrammatic representation (Fig. 4) gives the proportion in which the various colours of the hair are found among the professional classes and this was found to be a fair representation of other classes of the community. I have taken a record in Claybury Asylum (based upon this classification) of 2393 insane persons (see Table I.) of varying ages—viz., 1400 females and 993 males (see Table II.)—and my investigations yield almost similar results. There are, however, more black-brown males, but comparatively fewer men at the red end of the scale. The hair in the maximum number of men was dark-brown, and not brown as in Galton's table, whereas the women corresponded with the table and a higher percentage of women than of men had light-brown and red hair, as also grey and very grey hair (not in Galton's table), but there was a greatly preponderating number of bald-headed and very bald-headed persons among the men. This seems to indicate a more marked loss of self-control among fair females than among males, but a greater proportion of baldness (as among the sane) in men than in women. I took a further record of the colour of the hair among those who attended the entertainments and dances, and compared this record with that obtaining among those who attended Divine services (Table I.). A preponderance of very fair and brown-haired women attended the dances rather than church or chapel services, these

[2] Enquiries into Human Faculty, 1883.

*Influence of the operation upon pain* —Always excepting the cases already mentioned *all* the patients express themselves as being in less pain since than before the operation Many of them say that they are now quite free from pain (see Nos 3 6, 8 14 16 20 36 40 &c ) Some mention having slight discomfort after prolonged exercise (See Nos 1, 2 9 and 19) The effect of the operation upon the pain is then most marked and is nearly always entirely satisfactory

*Influence of the operation upon the veins* —Here we meet with considerable variation In no single case that I have seen has any increase of the varix or any new development of it been witnessed after the operation When we remember that in many cases there is a slow progression of varix for some years and notice the early age at which some of the operations were undertaken I think that we must acknowledge that we have here a distinct effect of the operation In many cases (see Nos 7, 13, 14 and 21) the operation is followed by the disappearance of the varices the subcutaneous veins exhibiting no departure from the normal In many others (see Nos 2 15 22 39 and 41) the varices shrink but do not disappear, they remain distinct but flaccid and less tense than before and as already said painless In a very small minority of cases the veins seem to be little if at all affected by the operation The veins in the thigh are more and more constantly affected than are those in the leg

*Influence of the operation upon thrombosis* —Some of the patients operated upon had suffered before the operation from recurring thrombosis It is certainly a most noteworthy point that the tendency to thrombosis seems to be very greatly lessened if not entirely removed by this operation In support of this statement I should like to mention one or two cases

CASE 4 —The patient was a woman 52 years of age, who had suffered very severely for many years from very extensive varices in both lower limbs She had for years worn elastic bandages from the feet to the groins and even with this support she was greatly hampered in her work as a nurse "never any comfort sitting standing or lying" Shortly before my operation in February, 1898 she had experienced four separate attacks of thrombosis which had kept her confined to bed for a long period and had greatly impaired her usefulness She has had no thrombosis since the operation she has lost all her pain has been able to dispense with the elastic bandages on the thighs and as she puts it she "hasn t felt so well for years as she does now" She is indeed very enthusiastic in her estimate of the value of the operation to her

CASE 5 —The patient was a healthy robust man 29 years of age who was sent to me by Dr J W Burton Fanning of Norwich His case was a little peculiar inasmuch as in addition to an enlarged internal saphena vein in the right thigh and numerous varices in the leg there was an enlarged vein running up the front of the thigh and entering apparently the circumflex iliac vein Pressure upon the saphena vein did not "control" the varices below unless this vein was also compressed This patient in addition to aching pains in the veins had suffered from several slight attacks of thrombosis just before he consulted me I ligatured and divided both of the veins in the thigh (No 49) and the result has been a distinct diminution in the size of the saphena vein and its tributaries but no such change in the other vein which seems to be "fed" by a deep communication about the middle of the thigh He is able to walk to ride to shoot to cycle and to play golf with comfort and he has had fewer and slighter attacks of thrombosis which now seems to have ceased

CASE 6 —This case is No 10 in the table The patient a woman 28 years of age had very frequent attacks of thrombosis—often every other month—up to the time of the operation Since then—a period of two and a quarter year — she has had two slight attacks only "very slight to what it used to be"

Where the varices are only "controlled" by pressure upon the external saphena vein as well as the internal I now obliterate the upper end of each vein, and I think that I have succeeded in benefiting cases by this means which in my earlier experience did not reap the full benefit of the operation

To sum up I would say that Trendelenburg s operation is not only a simple and safe proceeding but one that is very useful indeed in nearly all cases of varix It may be relied upon to relieve the aching pain so often felt it always stops further development of varices, it frequently leads to the shrinking or even to the disappearance, of varices and it exerts a strong influence in preventing thrombosis Its good effects are most pronounced where regurgitation into superficial veins is best marked Its superiority to excision of varices is greatest in cases of widely distributed and numerous varicose veins, for it exerts its influence upon all the veins emptying into the saphena trunks It is therefore useful in those widely distributed even general varicosities of the lower limbs for which excision is inapplicable To ensure success the vein or veins must be obliterated quite at their junction with the deep veins The fact that this operation has such a marked effect upon the course of varix is a strong proof of the important part that valvular defect plays in the history of cases of varicose veins

# GREY HAIR AND EMOTIONAL STATES
## AN ANTHROPOLOGICAL NOTE

BY ROBERT JONES, M D , B S LOND , F R C S ENG ,
RESIDENT PHYSICIAN TO AND SUPERINTENDENT OF THE LONDON COUNTY ASYLUM CLAYBURY

CASES of the hair turning "grey in a single night" are said occasionally to occur but it is uncommon to meet with well authenticated instances[1] The following case hardly comes under the category of "sudden blanching" as a period of five weeks in August and September last elapsed during which the hair and beard of this patient changed from a flecking of grey to absolutely pure white Owing to this change which an officer in charge of the patient described as having occurred "all at once, I hardly recognised the man upon my return after five weeks absence although I had seen him frequently, almost daily, since his admission into the asylum eight years before No other dermal or pigmentary changes occurred and there had been no affection of vision hearing or other of the special senses

The patient was a thin spare built man suffering from paranoia 53 years of age five feet eight inches in height and weighing 10 stones He was a clear complexioned, blue eyed intelligent and thoughtful looking man, with some reserve of manner For two or three months before admission into the asylum he gave way to drink as he had been much worried about his work in the electrical department of the General Post Office where he had been engaged for three years but during the whole time was "over trained" Previously to this he had been in India and Australia for about two years and with the above exception as to excessive use of alcohol was described as "always reserved and steady" He was married at the age of 23 years had never had syphilis and was said never to have had a day s illness in his life He developed delusions in regard to his occupation suspecting that a cable was connected with his house at a pressure of 10 000 volts, which would kill him his wife and his whole family (four children) He connected this persecution with those most intimately associated with him in bonds of affection and became aggressive and dangerous towards them Sleeplessness, fear and apprehensiveness preceded aural and sensory disturbances which dominated his reason and controlled his actions he became suicidal and was received into the Claybury Asylum in a low depressed condition with no appetite and very deluded The despondency increased he became feeble and emaciated and the delusions of persecution became very prominent He thought that he was being written about in all the papers He became violent very noisy abusive and aggressive and was for a time under the influence of either bromides, chloral or sulphonal He improved somewhat physically but latterly his emotional tone had become sombre and melancholy He stated that during the whole of August last a machine upon the roof shunted unbearable electrical currents upon him which so terrified him that he feared that each night would be his last as his life was to be destroyed He now talked less about his delusions—which however, still persisted—and he occupied enlargement presenting a rather large quantity of albumin in the urine while lying in bed which disappeared after they had been up for several hours. The albuminous urine was often high coloured, and, like the urine of backward pressure in cardiac disease, lithatic. In all my three cases he night urine was sometimes found to become free from lbumin.

---

[1] Dr B Thornton THE LANCET November 1891 Dr H Gr[illegible] Ives THE LANCET April 23rd (1901) and 30th (p 963) Drs Gould and Pyle Anomalies and Curiosities of Medicine

It is, of course, necessary that the bladder should be emptied of urine when the patient gets up, otherwise an admixture of the albuminous urine, excreted while in the recumbent position, with the normal urine of the erect position will occur, and the patient may be thought to have continuous albuminuria. The existence of this hypostatic albuminuria, if the term may be used, should be borne in mind when dealing with cases where, as in hospitals, the sample of urine provided for examination is taken from the whole amount passed in the 24 hours or is that passed early in the morning while the patient is in bed.

While the albuminuria is probably due to the mechanical pressure of the spleen on the left renal vein in the recumbent posture, the occurrence of this intermittent or hypostatic albuminuria is very far from constant in cases of splenic enlargement. In this it resembles albuminuria from chronic venous engorgement induced in other ways, as, for example, in the backward pressure of mitral disease. It does not depend on the size of the spleen, for hypostatic albuminuria may be, and, indeed, usually is, absent when the spleen is very large, and may be present, as in two of my three cases, where the spleen is relatively smaller. It is possible that its occurrence or absence may depend on some difference, such as elongation, in the condition of the suspensory peritoneal ligaments of the spleen which thus determine or prevent direct pressure on the left renal vein. On this point there is as yet no anatomical evidence. It is also conceivable that the appearance of albuminuria is dependent on an underlying want of vitality or nutrition in the kidney which, though not sufficiently marked to induce albuminuria under ordinary conditions, does so when chronic venous engorgement is superadded. This is to some extent supported by the observation that in one of the more recent cases albuminuria disappeared from the night urine after the patient had been some time in the hospital, and had somewhat improved under treatment; subsequently after a slight attack of influenza the night urine again contained albumin.

It appears that the appearance of albuminuria in the recumbent position and its disappearance in the erect position is not absolutely constant even in those individuals with enlarged spleen in whom its presence has been noticed; but its temporary occurrence in three cases justifies the suggestion that it may not be so very infrequent.

This hypostatic albuminuria is the reverse of what usually occurs in cyclical albuminuria, but it is possible that there may be some cases of cyclical albuminuria in which albumin appears when the patient is lying down and disappears when he is up. I have not yet met with a case, but the possibility of such an event is suggested by Edel's[3] recent observations that a weak pulse and the appearance of albumin in the urine in cyclical albuminuria are related, and that if, by regular muscular exertion, such as marching or hill-climbing, always stopping short of fatigue, the heart's action is strengthened, the urine becomes free from albumin, lighter in colour, and more copious.

Upper Brook-street, W.

A TOWN COUNCIL MUDDLE AT BULAWAYO.—At a meeting of the Bulawayo Town Council held on Jan. 20th, mention was made by the sanitary inspector of a case of typhoid fever the source of the infection of which could not be traced. The mayor stated that the advisability of appointing a medical officer of health would be discussed at a subsequent committee meeting. The disposal of slop and other contaminated water was also discussed. The chief sanitary inspector was asked to draw up a plan for dealing with the water, but it was eventually decided to postpone the matter. It is little more than a month ago since the Bulawayo Town Council decided, in pursuance of a "scheme of retrenchment," to abolish the office of medical officer of health as well as those of the town clerk and the town engineer. The chief sanitary inspector (acting town clerk) has resigned and the muddle thus created will certainly not help forward the health of the town.

# REMOVAL OF A SARCOMATOUS TUMOU FROM THE TAIL OF THE PANCREAS OF A CHILD FOUR YEARS AND EIGHT MONTHS OLD;

## SECONDARY GROWTH IN THE PORTAL VEIN.[1]

BY JOHN D. MALCOLM, M.B., F.R.C.S. EDIN.,

SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE following case seems sufficiently interesting and rare to be put on record.

The patient was a female child and was born on March 9th, 1894. Her father and mother are both alive and well; they have one other child, a healthy girl, born in 1897. One of the patient's grandfathers was said to have died from a internal cancer at the age of 65 years. The patient had whooping-cough when she was three weeks old. It was not known that she had suffered from any lung trouble. The bowels were very constipated whilst she was under immediate observation. There was no albumin in the urine, which was scanty (sometimes only 12 ounces in 24 hours), and deposited urates, its specific gravity being usually about 1030. An abdominal swelling was first noticed in April, 1898, and Dr. R. L. Guthrie sent the patient to a well-known surgeon who diagnosed a tumour of the left kidney but advised that no operation should be performed. Dr. Guthrie asked me to see the patient in May of the same year. She had then an obvious swelling in the upper part of the left side of the abdomen. It was firmly held in the position of a renal tumour, but the attachments seemed sufficiently lax to allow of the growth being shelled out of its bed. The patient was, however, extremely emaciated and anæmic, having a cachectic appearance which seemed to contra-indicate surgical interference, and I therefore agreed with the opinion and advice already given.

Dr. Guthrie treated the child with iron and laxatives, and in October, 1898, he asked me to see her again. She then had improved very much in her general condition, had quite a good colour, and was not thinner. The tumour ha increased in size, but not to any great extent. It distended the hollow of the left loin, pushing the lower ribs upwards and forwards, bulging the side outwards, extending across the abdomen as far as the outer edge of the right rectus muscle and downwards to below the level of the anterior superior iliac spines. The greatest girth of the body was 23¼ inches a little above the level of the umbilicus. On palpation the mass was smooth and elastic. It could be grasped between a hand in front of the abdomen and the other hand behind the loin, and although it was firmly held, there was still a slight mobility of the tumour, sufficient to make me think that I could remove it. There were some easily fe glands in both axillæ and in both groins, but they were no enlarged. The veins over the upper part of the abdomen were distended. No disease of the heart or lungs was detected. In view of the greatly improved condition of the child's general health I told the parents that she had a tumour of the kidney and explained that an operation would involve extreme risks. I also told them that I knew of only three cases in which after the successful removal of a tumour of this kind from a child the patient had survived more than a few months.[2] On the other hand, I pointed out that death must occur soon if nothing were done. It was decided to accept the risks of an operation.

On Nov. 4th, 1898, chloroform was administered and the tumour then seemed decidedly more mobile. I opened the abdomen through the upper part of the left linea semilunaris, and exposed the growth, with the splenic flexure and adjacent portions of the colon fixed in front of it. The most convenient place to open the retro-peritoneal space, in which the tumour lay, was above the transverse colon, and when the peritoneum in that situation was divided I had no difficulty in separating the tumour from the connective tissue in which it was loosely imbedded. Some firm adhesions to the lower end of the spleen were separated, and the new

| „ 75 „ 80 „ . .. | — | — | — |
| Totals ... ... . .. ... | 993 | 1400 | 2393 |

latter being of the darker, more sober, or atrabilious temperament, and this was also true of the men. In both sexes it was noticed that grey-haired persons attended services in preference to entertainments—the passive attitude of religious ministration being more appreciated by the old, whereas active indulgence in pleasurable pursuits prevailed among the young.

The influence of nervous changes upon the hair has not been fully worked out; but we are familiar with the harsh, dry hair and skin in melancholia, the sebaceous, oily condition of the latter in the dementia of general paralysis, and the up-standing shock of hair and peculiar odour of the skin emitted in certain cases of mania. Woods Hutchinson [3] insists that a due recognition of the "hereditary relationship and common ancestral origin" of the skin and cerebrospinal axis from the epiblastic layer of the blastoderm has been much overlooked, and also that the dignity and importance of the skin as an organ have not hitherto been fully acknowledged. The vaso-motor flushing of the skin in the mental disturbance of general paralysis, and the pinched, sallow look of melancholia, apart from the many changes that take place in the skin under normal mental states, indicate the control over it of the nervous system, as also over certain pigmentary changes such as accompany pregnancy, certain morbid utero-ovarian conditions and cachectic states (Addison's disease, cancer, &c.), and over the hair in certain diathetic conditions such as gout when the hair is thick but becomes white at a very early age. One of the most interesting papers by Lister to the Royal Society [4] was an experimental proof that the changes of colour in the skin of the frog were due to influences such as would excite the nervous system and that these influences were conveyed by nerves distributed to the skin. Normally the pigment is diffused naturally in the form of minute dark granules suspended in a colourless fluid in which those granules move freely throughout the cell and its branches, but when the skin becomes pale, as it does under the effect of stimulation or before death, the pigment accumulates in the centre of the cell The aggregation of the pigment-molecules can be excited at will either through the nerves directly or in a reflex manner by the stimulus of light upon the retina.[5] Upon those experiments Lister based his conclusion that the cerebro-spinal axis was chiefly, if not exclusively, concerned with regulating the functions of the pigment cells Further, Von Wittich also demonstrated many years previously to this experiment that the movement of pigment granules was dependent upon the nervous system It has not been precisely accepted what the organic changes are which occur in the progress of the growth of a hair. A slow permeation of a fluid from the root to the point of the hair has been stated to occur, and when this ceases from any sudden cause, such as the devitalising shock of a strong emotion, air lacunules occur in the cortical layers of the hair with a consequent appearance of whiteness.[6] Indeed, the air cells so abundantly found in the fibrous or cortical layer of white hairs, and not the absence of pigment only, are said to give them their characteristic appearance,[7] although the same appearance may certainly be due also to a general lack of pigment—as is noticed in the congenital defect known as albinism. It is noteworthy that although white hair is compatible with vigorous and perfect health, as is witnessed in the winter-whitening[8] of the fur of animals inhabiting polar regions, this is not the case with albinism which is generally accompanied by a marked deficiency of vital force—deafness often occurring in cats, defects of eye sight in horses, and both combined in human beings. In the winter-whitening of arctic birds and foxes this change is an adaptability to environment, enabling them either to avoid their enemies or to deceive their prey, and it is stated to occur instantaneously and to be determined by some sudden natural phenomenon, such as a fall of snow, which has an immediate correlative effect upon the nervous system of the animal, indicating the necessity of an equally sudden adaptation to its changed surroundings. May not such cases as that recorded by Staff Surgeon Parry (under his actual observation)[9] of sudden blanching through intense emotion be analogous to the change which is known to occur naturally in the lower animals, and thus be one of those reversions which we still meet with in the physical and mental deterioration of human beings, also indicating that a sudden influence through the nervous system is brought to bear upon the organism, necessitating sudden transformation if this organism is to continue its existence under its new environment? Whatever explanation is offered of sudden blanching, which without doubt does occasionally occur, the close physiological connexion between the cerebro spinal axis and the skin, which have a common genealogy, must be borne in mind; also (as already pointed out in the frog) the dominating control of the nervous over the pigmentary system in the batrachian may have a like influence in man. Finally, this nervous control when disturbed may exercise a correlative disturbance upon the baser tissues.

# A NOTE ON HYPOSTATIC ALBUMINURIA OF SPLENIC ORIGIN.[1]

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,

PHYSICIAN TO, AND LECTURER ON PATHOLOGY AT, ST. GEORGE'S HOSPITAL; EXAMINER IN MEDICINE TO THE UNIVERSITY OF DURHAM.

THIS short communication deals with a small point which has very probably often been observed before, but being an isolated observation has not been thought worthy of much notice The point, to which I wish to draw attention, is that in some patients with considerable splenic enlargement, rest in bed or in the recumbent position may be accompanied by albuminuria, and that the albumin may disappear from the urine when the patient assumes the erect position. This fact was first brought to my notice in a case of advanced leukæmia which I often saw with Dr. C. J. Heaton of Westgate-on-Sea who drew attention to the intermittent albuminuria and explained it on Falkenheim's[2] suggestion that in the recumbent position the spleen pressed on the left renal vein, interfered with the return of venous blood from the kidney and thus gave rise to albuminuria. This seems to be a very reasonable explanation of the occurrence. I have recently had under my care two other patients, with hepatic cirrhosis and splenic anæmia respectively, with considerable splenic enlargement presenting a rather large quantity of albumin in the urine while lying in bed which disappeared after they had been up for several hours. The albuminous urine was often high coloured, and, like the urine of backward pressure in cardiac disease, lithatic. In all my three cases the night urine was sometimes found to become free from albumin.

---

[1] A paper read at the meeting of the Medical Society of London on Feb. 24th, 1902.

[2] Falkenheim (Deutsches Archiv fur Klinische Medicin, Band xxxv., S 446, 1884) described exactly this condition in a man, aged 50 years, with hepatic cirrhosis and a large spleen. He observed that lying on the right side and on the abdomen did not induce albuminuria.

It is, of course, necessary that the bladder should be emptied of urine when the patient gets up, otherwise an admixture of the albuminous urine, excreted while in the recumbent position, with the normal urine of the erect position will occur, and the patient may be thought to have continuous albuminuria. The existence of this hypostatic albuminuria, if the term may be used, should be borne in mind when dealing with cases where, as in hospitals, the sample of urine provided for examination is taken from the whole amount passed in the 24 hours or is that passed early in the morning while the patient is in bed.

While the albuminuria is probably due to the mechanical pressure of the spleen on the left renal vein in the recumbent posture, the occurrence of this intermittent or hypostatic albuminuria is very far from constant in cases of splenic enlargement. In this it resembles albuminuria from chronic venous engorgement induced in other ways, as, for example, in the backward pressure of mitral disease. It does not depend on the size of the spleen, for hypostatic albuminuria may be, and, indeed, usually is, absent when the spleen is very large, and may be present, as in two of my three cases, where the spleen is relatively smaller. It is possible that its occurrence or absence may depend on some difference, such as elongation, in the condition of the suspensory peritoneal ligaments of the spleen which thus determine or prevent direct pressure on the left renal vein. On this point there is as yet no anatomical evidence. It is also conceivable that the appearance of albuminuria is dependent on an underlying want of vitality or nutrition in the kidney which, though not sufficiently marked to induce albuminuria under ordinary conditions, does so when chronic venous engorgement is superadded. This is to some extent supported by the observation that in one of the more recent cases albuminuria disappeared from the night urine after the patient had been some time in the hospital, and had somewhat improved under treatment; subsequently after a slight attack of influenza the night urine again contained albumin.

It appears that the appearance of albuminuria in the recumbent position and its disappearance in the erect position is not absolutely constant even in those individuals with enlarged spleen in whom its presence has been noticed; but its temporary occurrence in three cases justifies the suggestion that it may not be so very infrequent.

This hypostatic albuminuria is the reverse of what usually occurs in cyclical albuminuria, but it is possible that there may be some cases of cyclical albuminuria in which albumin appears when the patient is lying down and disappears when he is up. I have not yet met with a case, but the possibility of such an event is suggested by Edel's[3] recent observations that a weak pulse and the appearance of albumin in the urine in cyclical albuminuria are related, and that if, by regular muscular exertion, such as marching or hill-climbing, always stopping short of fatigue, the heart's action is strengthened, the urine becomes free from albumin, lighter in colour, and more copious.

A TOWN COUNCIL MUDDLE AT BULAWAYO.—At a meeting of the Bulawayo Town Council held on Jan. 20th, mention was made by the sanitary inspector of a case of typhoid fever the source of the infection of which could not be traced. The mayor stated that the advisability of appointing a medical officer of health would be discussed at a subsequent committee meeting. The disposal of slop and other contaminated water was also discussed. The chief sanitary inspector was asked to draw up a plan for dealing with the water, but it was eventually decided to postpone the matter. It is little more than a month ago since the Bulawayo Town Council decided, in pursuance of a "scheme of retrenchment," to abolish the office of medical officer of health as well as those of the town clerk and the town engineer. The chief sanitary inspector (acting town clerk) has resigned and the muddle thus created will certainly not help forward the health of the town.

# REMOVAL OF A SARCOMATOUS TUMOUR FROM THE TAIL OF THE PANCREAS OF A CHILD FOUR YEARS AND EIGHT MONTHS OLD;

## SECONDARY GROWTH IN THE PORTAL VEIN.[1]

BY JOHN D. MALCOLM, M.B., F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE following case seems sufficiently interesting and rare to be put on record.

The patient was a female child and was born on March 9th, 1894. Her father and mother are both alive and well; they have one other child, a healthy girl, born in 1897. One of the patient's grandfathers was said to have died from an internal cancer at the age of 65 years. The patient had whooping-cough when she was three weeks old. It was not known that she had suffered from any lung trouble. The bowels were very constipated whilst she was under immediate observation. There was no albumin in the urine, which was scanty (sometimes only 12 ounces in 24 hours), and deposited urates, its specific gravity being usually about 1030. An abdominal swelling was first noticed in April, 1898, and Dr. R. L. Guthrie sent the patient to a well-known surgeon who diagnosed a tumour of the left kidney but advised that no operation should be performed. Dr. Guthrie asked me to see the patient in May of the same year. She had then an obvious swelling in the upper part of the left side of the abdomen. It was firmly held in the position of a renal tumour, but the attachments seemed sufficiently lax to allow of the growth being shelled out of its bed. The patient was, however, extremely emaciated and anæmic, having a cachectic appearance which seemed to contra-indicate surgical interference, and I therefore agreed with the opinion and advice already given.

Dr. Guthrie treated the child with iron and laxatives, and in October, 1898, he asked me to see her again. She then had improved very much in her general condition, had quite a good colour, and was not thinner. The tumour had increased in size, but not to any great extent. It distended the hollow of the left loin, pushing the lower ribs upwards and forwards, bulging the side outwards, extending across the abdomen as far as the outer edge of the right rectus muscle and downwards to below the level of the anterior superior iliac spines. The greatest girth of the body was 23¾ inches a little above the level of the umbilicus. On palpation the mass was smooth and elastic. It could be grasped between a hand in front of the abdomen and the other hand behind the loin, and although it was firmly held, there was still a slight mobility of the tumour, sufficient to make me think that I could remove it. There were some easily felt glands in both axillæ and in both groins, but they were not enlarged. The veins over the upper part of the abdomen were distended. No disease of the heart or lungs was detected. In view of the greatly improved condition of the child's general health I told the parents that she had a tumour of the kidney and explained that an operation would involve extreme risks. I also told them that I knew of only three cases in which after the successful removal of a tumour of this kind from a child the patient had survived more than a few months.[2] On the other hand, I pointed out that death must occur soon if nothing were done. It was decided to accept the risks of an operation.

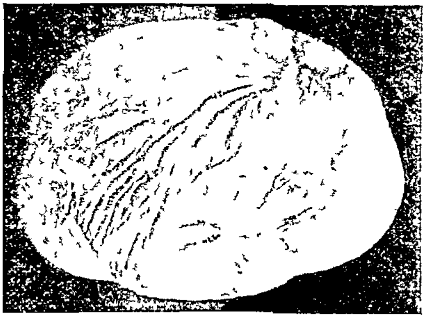
On Nov. 4th, 1898, chloroform was administered and the tumour then seemed decidedly more mobile. I opened the abdomen through the upper part of the left linea semilunaris, and exposed the growth, with the splenic flexure and adjacent portions of the colon fixed in front of it. The most convenient place to open the retro-peritoneal space, in which the tumour lay, was above the transverse colon, and when the peritoneum in that situation was divided I had no difficulty in separating the tumour from the connective tissue in which it was loosely imbedded. Some firm adhesions to the lower end of the spleen were separated, and the new growth was then easily drawn out of the abdominal cavity, the tail of the pancreas being dragged out with it The tumour was then only attached to the pancreas and it was impossible to separate them without cutting through pancreatic tissue In doing this large vessels were divided, but hæmorrhage from them was easily controlled by ligatures. No ureter was seen during the operation There was a second new growth of about the size of a bantam's egg to the right of the cavity from which the tumour had been removed I thought that this was a collection of glands affected by malignant disease, but the patient was in such a serious state of collapse that it was out of the question to attempt an investigation of the nature and connexions of this second abnormal condition I therefore ligatured all bleeding points having much trouble in securing those on the spleen. I washed out the abdominal cavity with warm sterilised salt and water, leaving as much as possible inside, when the wound was sewn up, with a view to counteracting the shock of the operation, which, however, was not survived by the patient

---

[1] A paper communicated to the Pathological Society on Feb. 18th, 1902.

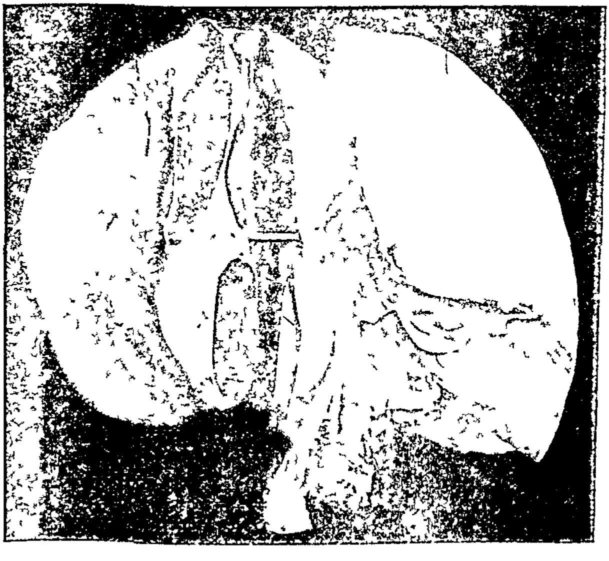
[2] The patient in one of these cases, which was published by myself in the Transactions of the Clinical Society of London, 1894 and 1895, is alive and well, more than nine years after the operation.

FIG 1



Tumour removed from the tail of the pancreas The figure is about half the actual size of the tumour which measured five inches in its longest diameter No 2336A, Royal College of Surgeons of England Museum

FIG 2



Under surface of the liver, parts of the stomach duodenum and gall bladder and the divided portal vein greatly distended In dividing the vein the tumour also was divided into two unequal parts the larger of which nearer the liver end of the vein was found to be quite unattached and has been removed a considerable portion of the remaining part of the tumour is also obviously unattached The vein was not occluded a bristle is seen passing by the side of the tumour through the lower portion of the vessel (Half size) No 2336B, Royal College of Surgeons of England Museum

At the necropsy, which was conducted by Dr Cuthbert H J Lockyer, caseating glands were found near the bifurcation of the bronchi and in the anterior mediastinum There were extensive old pleuritic adhesions on the right side There was no sign of peritonitis or of union of the lips of the wound The peritoneal cavity was full of fluid (the salt and water introduced at the operation), which at first flowed away clear, but that from the loin pouches was deeply blood stained The kidneys were healthy and were normal in position Part of the transverse colon was separated from its attachments its meso colon having been completely divided, and the omentum had been removed from all but the left one and a half inches of the stomach The left pleuro colic fold was intact The spleen had a wound on the lower end of its inner surface one and a half inches long The left half of the pancreas was absent, its cut surface presenting many ligatured points There was a smooth encapsuled growth situated in the gastro hepatic omentum with the bile duct and some vessels in front of it The neck of the gall bladder, and the transverse fissure of the liver were above it The foramen of Winslow was behind and the new growth seemed to be connected with the head of the pancreas below, the connexion between the two being much constricted

The parts were sent to the Royal College of Surgeons of England and when they had been dissected it was found that the mass in the lesser omentum was a new growth inside the portal vein and widely distending it. Mr Shattock has examined the tumours and both are fibro-sarcomatous in structure The specimens are preserved in the museum of the College and the accompanying illustrations (Figs 1 and 2), which are reproduced from photographs taken by Mr. H. George, give a very faithful representation of their appearance.

Although the nature of the tumour removed in this case was doubtful even at the end of the operation the conditions found at the post-mortem examination of the body showed that it certainly had grown from the pancreas, from which it had been noted that the chief blood supply of the new growth came; a larger portion of pancreas had been removed than I thought when operating. The differential diagnosis between an enlarged kidney and a tumour of the tail of the ancreas may be quite impossible. Once before[3] I operated n a tumour having almost exactly the same relations as in is case to the tail of the pancreas and to the surrounding uctures, and I was assisted in mistaking the tumour for a renal enlargement by three of the most experienced men in London. I removed a cystic tumour, having to divide the pancreatic tissue as in the case now recorded. In that case I examined the parts during the operation, and found the kidneys and spleen in their normal positions. The patient made a good recovery, is still alive, and has had no further trouble from the tumour or from the operation. In neither of these cases was there any difficulty in arresting hæmorrhage from the pancreatic tissue, although in the first case there was much trouble in finding a bleeding point. In the present case it did not seem to me that there was any great difficulty in arresting hæmorrhage from the torn spleen by pressure or even by ligatures except that it was very far from easy to expose the parts to view. But the presence of an obstruction in the portal vein and the fact that towards the end of the operation the patient was in a state of extreme collapse render observations on this point of little value in this case. It is obvious that no operation could have cured the patient, but it was not possible to discover the smaller secondary growth until the larger one was extracted. I was right, however, in considering that the tumour diagnosed was removeable. If there had not been a secondary growth there would have been a very fair prospect that the patient might have done well, and I regret that I did not recommend operative treatment when I first saw the child.

Portman-street, W.

# GENERAL REMARKS ON ASYLUM DYSENTERY AND ITS TREATMENT BY INJECTIONS OF PERMANGANATE OF POTASH.

BY P. W. MACDONALD, M.D. ABERD.,

MEDICAL SUPERINTENDENT, DORSET COUNTY ASYLUM.

AT a time when attention is being directed to irrigation of the bowel as a successful method of treating dysentery and allied conditions mainly in the light of experience gained during the South African campaign, it may be of interest to give a few details of the treatment of this troublesome complaint by means of injections of permanganate of potash.

Asylum dysentery, or so-called "colitis," has of late years been a source of much anxiety in many of the institutions for the insane in this country. The subject has been fully and lucidly dealt with by several able writers, but beyond mentioning the stock remedies the question of treatment has occupied a subsidiary place. The main object of the numerous workers, in what threatens to turn out a somewhat unprofitable field of research, would seem to be the elucidation of the causation and spread of this vexatious and recurring complaint At a recent meeting of the Epidemiological Society, the whole subject was re-discussed in all its bearings, and the two points on which there seemed to be a general agreement were the spread of the complaint by the removal of patients from one institution to another and the infectious nature of the disease as evidenced by its occurrence among patients sleeping in dormitories. While dysentery has been more common in asylums of late years than formerly, it must not be supposed that it is a new complaint in these institutions. There are records and particulars of its occurrence in asylums long before the present-day ideas of germs, bacilli, &c., were promulgated. Numerous as have been the attempts to trace the origin and spread of dysentery in asylums no very clear or definite ideas have yet been arrived at. Overcrowding, sanitation, ventilation, and so on, have respectively been penalised, but there is no consensus of opinion why dysentery should have become a troublesome complaint in a latter-day nineteenth-century asylum, and that, too, where none of the causes already mentioned exist. Defects in sanitary arrangements would be sufficient, but often none exist, and the attempts to associate the disease with a certain well-known system of warming and ventilation have completely failed. As regards overcrowding there are numerous instances of its appearance where overcrowding did not exist. At the same time, where there is congestion of space, if not actual overcrowding, the conditions are favourable, and if there is associated with these the unnatural craving for warming dormitory space I am of opinion that a fair explanation is offered for the occurrence of many cases of dysentery. In round numbers th fourths of asylum patients are physically hale and hea and should not, and do not, require artificially warmed spa after 8 P.M.

During the autumn of 1899 and the spring of 190 dysentery appeared in the Dorset County Asylum, and while the cases were not numerous, yet they were sufficient in number to cause inconvenience and anxiety. Starting on the female side, the cases were of the usual well-known type and character and the number of severe attacks were in about the usual proportion. After a time, and when there were no cases in the women's wards, cases began to appear on the male side, and these, if fewer in number, were more severe than among the women. At this time the ordinary therapeutic remedies were employed and in a few cases injections of a solution of nitrate of silver were tried, but the results were most discouraging. As far as practicable the cases were isolated and the complaint disappeared from our midst, only to reappear again in the winter of 1900. It was during this second outbreak that the use of injections of permanganate of potash was resorted to. As soon as the case was diagnosed to be one of dysentery the lower bowel was washed out night and morning with a weak solution (from two to four grains to th pint) of permanganate, the instrument used being an ordinary enema syringe. The motions rapidly lessened and seldom had the treatment to be prolonged beyond the third day. In every one of the cases—and several of them were severe—the patients recovered. Not only was the treatment successful, but by the early and judicious use of the injections the outbreak was cut short. At the time doubts were entertained as to the value of the treatment, but after a further experience these doubts were removed and now every case of a dysenteric nature or of severe diarrhœa is treated by this method. In each instance recovery has followed the treatment. Apparently the permanganate acts in its double capacity of a disinfectant and a styptic. In the more severe cases milk as an article of diet was found to be unsatisfactory. It was not only rejected but it increased the intestinal irritation. This, I believe, is not an uncommon experience. The main article of diet used was a mixture of special beef-tea and specially prepared rice, together with a liberal allowance of port wine. To ensure success the treatment should be commenced early and thoroughness is an essential precaution. In one case only after the permanganate treatment had been adopted has there been an opportunity of examining the bowel post mortem. This was the case of a demented melancholic who had a very severe attack of dysentery from which she made an excellent recovery. The injections were continued for five days and the patient was quite convalescent in three weeks. Soon afterwards she developed acute double pneumonia to which she succumbed. At the necropsy the mucous membrane of the rectum showed numerous healed ulcers, so different from the ulcerated congested state of the bowel in fatal cases from dysentery. Two classes of patients—the tuberculous and the general paralytic—invariably give bad results. The reason is too evident to need any explanation

While my experience of the permanganate has not been extensive I think it has been sufficient to warrant the results being made known and I am hopeful that this short paper may be the means of inducing others to try the treatment as opportunity occurs.

Dorchester.

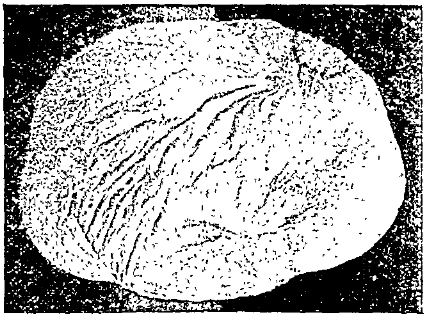
[3] Transactions of the Medical Society of London, 1893.

growth was then easily drawn out of the abdominal cavity, the tail of the pancreas being dragged out with it. The tumour was then only attached to the pancreas and it was impossible to separate them without cutting through pancreatic tissue. In doing this large vessels were divided, but hæmorrhage from them was easily controlled by ligatures. No ureter was seen during the operation. There was a second new growth, of about the size of a bantam's egg to the right of the cavity from which the tumour had been removed. I thought that this was a collection of glands affected by malignant disease, but the patient was in such a serious state of collapse that it was out of the question to attempt an investigation of the nature and connexions of this second abnormal condition. I therefore ligatured all bleeding points, having much trouble in securing those on the spleen. I washed out the abdominal cavity with warm sterilised salt and water, leaving as much as possible inside, when the wound was sewn up, with a view to counteracting the shock of the operation, which, however, was not survived by the patient.

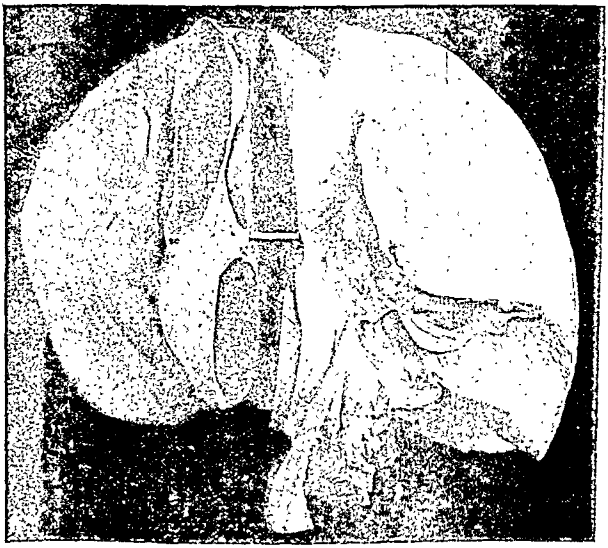
FIG. 1.



Tumour removed from the tail of the pancreas. The figure is about half the actual size of the tumour which measured five inches in its longest diameter. No. 2336A, Royal College of Surgeons of England Museum.

At the necropsy, which was conducted by Dr. Cuthbert H. J. Lockyer, caseating glands were found near the bifurcation of the bronchi and in the anterior mediastinum. There were extensive old pleuritic adhesions on the right side. There was no sign of peritonitis or of union of the lips of the wound. The peritoneal cavity was full of fluid (the salt and water introduced at the operation), which at first flowed away clear, but that from the loin pouches was deeply blood-stained. The kidneys were healthy and were normal in position. Part of the transverse colon was separated from its attachments, its meso-colon having been completely divided, and the omentum had been removed from all but the left one and a half inches of the stomach. The left pleuro-colic fold was intact. The spleen had a wound on the lower end of its inner surface one and a half inches long. The left half of the pancreas was absent, its cut surface presenting many ligatured points. There was a smooth encapsuled growth situated in the gastro-hepatic omentum with the bile-duct and some vessels in front of it. The neck of the gall-bladder, and the transverse fissure of the liver were above it. The foramen of Winslow was behind and the new growth seemed to be connected with the head of the pancreas below, the connexion between the two being much constricted.

FIG. 2.



Under surface of the liver, parts of the stomach, duodenum, and gall-bladder and the divided portal vein greatly distended. In dividing the vein the tumour also was divided into two unequal parts, the larger of which, nearer the liver end of the vein, was found to be quite unattached and has been removed; a considerable portion of the remaining part of the tumour is also obviously unattached. The vein was not occluded; a bristle is seen passing by the side of the tumour through the lower portion of the vessel. (Half size.) No. 2336B, Royal College of Surgeons of England Museum.

The parts were sent to the Royal College of Surgeons of England and when they had been dissected it was found that the mass in the lesser omentum was a new growth inside the portal vein and widely distending it. Mr. Shattock has examined the tumours and both are fibro-sarcomatous in structure. The specimens are preserved in the museum of the College and the accompanying illustrations (Figs. 1 and 2), surface becomes dulled by deposition of moisture upon it and the image is blurred. And this is apt to occur when the operator requires to have the part which is being operated upon most clearly in sight. Again, when electric light is used as the source of illumination the mirror must be warmed by holding it before a fire, over a spirit-lamp, or placed in hot water. The first two methods are inconvenient and not always within reach and the last is deleterious to the mirror. All laryngologists are painfully aware of the rapid destruction of mirrors regularly heated by immersion in hot water. To overcome this difficulty several methods, such as smearing the mirror with glycerine, &c., have been tried, but all of them so interfered with the reflecting quality of the mirror that they proved useless in practice.

Lately, and somewhat by accident, I fell upon the following plan, and it has been so eminently successful that I desire to call the attention of laryngologists particularly to it. An ordinary laryngeal mirror is taken and after polishing it with a soft cloth the surface of the mirror is rubbed or pencilled over with "*le crayon anti-buée*." This dulls the surface. The mirror is again wiped or polished with a soft cloth and the surface will again be clear and bright. It may then be breathed upon without its brightness being affected. After being so prepared the mirror may be used for laryngoscopical examination, and it may be retained in contact with the palate or in any part of the buccal or pharyngeal cavities as long as may be desired, or, as is ever necessary, without the reflecting surface being affected in the slightest degree by the breath-borne moisture. The crayon causes no scratching of the glass nor does its use interfere with the cleansing and sterilising of the mirror. I do not employ this method to the exclusion of heat, as the latter is much too convenient to be lightly discarded, but this method of preserving a clear, bright, reflecting surface will be found of great service under the following circumstances—namely, (1) in an examination to be made with electric light; (2) where a prolonged use of the mirror is necessary; (3) in examinations made away from home; and (4) in the examination of children whose timidity is so often increased by seeing the mirror held over the flame of the lamp before being used. Dentists may also find the "crayon" to be useful, and the eye-piece of a microscope may be kept perfectly clear and bright, even during a prolonged examination in warm weather. The crayon may be obtained in Glasgow from Messrs. W. B. Hilliard, 63, Renfield-street.

Glasgow.

# HOSPITAL PRACTICE, BRITISH AND FOREIGN.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

## ST. GEORGE'S HOSPITAL.

### TWO CASES OF GASTRIC SURGERY.

(Under the care of Mr. HERBERT W. ALLINGHAM.)

THE modern treatment of gastric ulcer is in striking contrast to that which was employed only a few years ago. A chronic ulcer of the stomach may reasonably be submitted to operation if it has materially interfered with digestion and nutrition, even though no hæmatemesis may be present. The first of the following two cases is an excellent example of this recent surgical advance. In the second case pyloroplasty was employed for a fibrous stenosis of the pylorus. This operation has been somewhat discredited lately, chiefly because it has been performed in unsuitable cases. Koeppelin's "submucous pyloroplasty,"[1] though perhaps safer than the ordinary operation, must be of more limited applicability.

CASE 1. *Excision of a gastric ulcer.*—A woman, aged 34 years, was admitted into St. George's Hospital on Oct. 29th with a history that for about eight years she had suffered from pain in the stomach after food. The pain, which was severe and prevented her from following her occupation, came on immediately after food, as a rule, but at times was not felt until from half to one hour had elapsed. She was unable to take solid food without vomiting, but hæmatemesis had only occurred once about seven years previously. She had never passed blood by the bowel, but was always very constipated. She was not emaciated. On examining the abdomen nothing abnormal was found except slight tenderness which was always present at one particular spot in the epigastrium. Seeing that the condition had existed for so long and had persisted in spite of medical treatment operation was advised. On Nov. 7th Mr. Allingham made an incision in the middle line above the umbilicus and opened the abdomen. The stomach was drawn out and on the anterior wall a puckered mass of thickened tissue of about the size of a shilling was found. It was covered with lymph and was slightly adherent to the surrounding parts. The peritoneum having been protected by means of sponges the ulcer and the tissues immediately around were excised and the wound in the stomach was sewn up by means of two rows of sutures, the mucous membrane being first brought together and then the muscular coats and the peritoneum. In the latter Lembert's method was employed and in both rows silk alone was used. The abdomen was then closed without drainage. Recovery was uneventful, the wound healing by first intention and the patient left the hospital on Nov. 30th, having taken solid food without pain or discomfort for 14 days before her discharge.

CASE 2. *Pyloroplasty for pyloric stenosis caused by nitric acid.*—A man, aged 37 years, was admitted into St. George's Hospital on August 28th, under the care of Dr. Latham, complaining of constant vomiting and pain after food, which had existed for seven weeks, during which time he had been unable to retain any solids. Whilst under observation the vomiting only occurred about once every two days and after a few days, during which time he was fed on peptonised food, it ceased altogether. He stated that he had vomited blood on one occasion on August 10th, but never since. On examination of the abdomen the stomach was found to be much dilated, and the abdominal muscles were rigid and moved but slightly on respiration and he complained of some tenderness in the epigastrium. After some days he volunteered the statement that he had swallowed a quantity of nitric acid on July 16th in mistake for ginger beer and had never been well since. He looked ill and was a good deal wasted, but improved somewhat under treatment—i.e., stomach lavage and careful feeding; the dilatation of the stomach, however, did not diminish, so on Sept. 24th Mr. Allingham operated. The stomach was washed out immediately before the operation and 70 ounces were drawn off. By the phloroglucin-vanillin test no free hydrochloric acid was found in the vomited material. The abdomen having been opened in the middle line above the umbilicus the stomach was drawn out of the wound. It was much dilated and the pylorus was thick and hard. There were no adhesions. A longitudinal incision was made over the pylorus and the lumen was only found by means of a probe. The tissues of the stomach at the pyloric end were exceedingly tough and fibrous. Pyloroplasty was performed in the ordinary way and the wound was sutured in two layers over one of Allingham's bone-bobbins. The patient made an uninterrupted recovery and was discharged from the hospital on Oct. 22nd, having been able to take solid food without pain, discomfort, or sickness for some days previously.

*Remarks by* Mr. C. R. KEYSER.—Case 1 serves to illustrate several points which are gradually becoming recognised. In the first place, in cases of gastric ulcer which have resisted medical treatment and in which the patient is rendered a chronic invalid, or vomiting and hæmatemesis are constant, operation should be undertaken much earlier than has hitherto been the custom. The complications of gastric ulcer are so numerous and dangerous that, according to recent statistics,[2] 25 per cent. of all cases treated medically terminate fatally, whereas the mortality of those surgically treated is only 5 per cent., and it is practically certain that if, instead of waiting until the patients are emaciated and worn out with suffering, operation was resorted to at a comparatively early date, the mortality would be reduced still further. The operation which will be necessary depends entirely on the condition found after opening the abdomen and examining the stomach, and may be either excision of

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### GENERAL RESTRICTION OF DIET IN DIABETES.

BY G. S. KEITH, M.D., F.R C.P. EDIN.

THIS brief outline of a case of diabetes which has recently been under my care may be of interest to the readers of THE LANCET inasmuch as it bears out the beneficial results of a method of treatment which I have advocated for many years. In its results, however, it is no whit more satisfactory than I have found to be the case in innumerable instances of divers diseases which have been described in my "Plea for a Simpler Life" and "Fads of an Old Physician"

The patient, a man, aged 38 years, had resided for several years in a tropical but not unhealthy climate. He came home early last year as the heat did not seem to suit his health and since then he has been living in North Berwick where he could enjoy his favourite game of golf. He there consulted a medical man and was told that the immoderate thirst from which he was suffering was due to diabetes. The specific gravity of his urine was then found to be 1037. Subsequently he was advised to consult a London specialist who put him on the usual anti-diabetic diet. He was ordered to abstain from everything which contained starch or sugar and was given a long list of animal and albuminous foods in which he could indulge. No restriction whatever was put on the quantity of these and, further, he was recommended to take fatty substances *ad libitum*, with the view of restricting the waste of tissue which was going on very rapidly. He soon found that the fats which he consumed in large quantity did not agree with him and his medical adviser in Edinburgh advised him to discontinue their use; this he did with marked benefit.

I first saw the patient about the middle of October, 1901. He had then lost about two stones in weight, but his muscular strength was only slightly impaired, and he was still able to enjoy a game of golf. He had, however, an intense craving for food, suffered from severe thirst, and was likewise passing a very large quantity of urine. I recommended him, therefore, to reduce as rapidly as possible the total nitrogenous intake, and at the same time to introduce a small quantity of bread into his dietary. I saw him again three weeks later and during the interval he had reduced his total food to a very moderate allowance, while for the last week he had taken for breakfast a couple of ounces of bread which he enjoyed amazingly The craving for food and water had practically disappeared, while the amount of urine was now reduced to two and a half pints. An analysis of a sample gave the following results specific gravity, 1019; albumin, *nil;* and sugar, 0·32 per cent. His weight had increased in three weeks by six pounds—a fact which, as I pointed out to him, was no doubt owing to the retention in the system of water which had previously served as the vehicle for the discharge of waste products and in this way had been lost to the tissues. He now resolved to return to the tropics in order to resume the duties which he thought he had finally relinquished I saw him again two months later (Jan. 6th, 1902) and found that he had made arrangements to leave the country in the middle of the month. In the meantime he had a slight return of his former symptoms, owing probably to the fact that while still reducing his animal food he had indulged somewhat too freely in farinaceous and sweet articles of diet. On the adoption of the dietetic restrictions previously ordered the symptoms once again rapidly disappeared, and at the present moment he is on the point of carrying out his original intention of resuming work.

The interest of this case centres in the remarkable amelioration of the diabetic symptoms which followed a general restriction of diet without reference to particular elements of food. This is nothing new in face of my past experience and I attribute it, as I have endeavoured to show in my published works, to the curative influence of a restricted diet, more especially with regard to nitrogenous foodstuffs.

Currie, Midlothian.

### A CASE OF INFECTIVE PERIOSTITIS.

BY JOHN R GRIFFITH, M.R C.S. ENG., L.R.C.P. LOND.

A SHORT time ago I attended a child suffering from the above disease and as the case presented, to my mind, one or two interesting features I think it is worth recording.

The patient, a female child, aged 11 years, who had always enjoyed robust health, had been "out of sorts" for two or three days The morning on which I first saw her she had a rigor, and on examination her condition indicated a severe constitutional disturbance. The temperature was 103° F., the pulse was 120, the tongue was furred, and the breathing was quick. On inquiry the mother gave the information that the child did not complain of pain in any particular region and for a short time I was nonplussed to account for the constitutional disturbance. On further examination it was discovered that the child had a double talipes—i.e., right talipes equino-varus and left talipes equinus. Further, a puffiness located over the internal malleolus of the right leg was noticed. The veins were swollen, but the child did not cry out when the afflicted leg was being manipulated. I noticed that the vulva was inflamed and a purulent discharge was seen about the vulval orifice. The next morning (the second day) the general condition of the child was worse; the temperature was 104°, the breathing was rapid, and the usual symptoms which accompany pyrexia were present. On examining the afflicted leg it was noticed that the swelling had much increased, the whole of the shaft of the tibia being implicated up to the tubercle. The skin was becoming dusky red in colour, pitting on pressure, and the child now was in evident agony on the least handling. The nature of the case was fully explained to the parents and the necessity of an immediate operation having been fully laid before them they consented to its being carried out. Later in the morning my principal, the late Mr. D. E. Edwards of Llwynypia, and myself went to the house fully prepared to lay bare the whole shaft and to gouge parts of it away if thought necessary. The parents by this time had changed their minds and they absolutely refused treatment; therefore nothing was done. The condition of the patient went from bad to worse; on the third morning septic pleurisy supervened, and on the fourth pericarditis, and she died at 11 o'clock the same night.

The child, at any time of her existence, had not been treated for the talipes. I ascertained from the mother that the child was in the habit of falling about in walking and especially on trying to run. This undoubtedly accounts for the injury constituting one cause of the periostitis.

The point of interest of the case which appeals to me is whether one is justified in thinking that the entry of the virulent streptococci and staphylococci was through the vagina from this purulent discharge. The child had never had typhoid fever.

Blackwood, Mon.

### A METHOD BY WHICH DEPOSITION OF MOISTURE ON THE LARYNGEAL MIRROR MAY BE PREVENTED WITHOUT THE AID OF HEAT.

BY WALKER DOWNIE, M.B., F.F.P.S. GLASG.,
LECTURER ON DISEASES OF THE THROAT AND NOSE, GLASGOW UNIVERSITY.

WHEN about to make a laryngoscopic examination by means of reflected light the laryngeal mirror is warmed before being passed into the mouth with the object of preventing condensation of moisture from the breath on its reflecting surface When gas or oil is used as the illuminant the warming of the mirror by holding it over the flame is simple, very convenient, and eminently satisfactory for routine examination, and is quite devoid of risk so long as the examiner is careful to test the temperature of the mirror before passing it into the buccal cavity.

But if the mirror so warmed be retained for some time in the pharynx, as is frequently necessary during delicate intralaryngeal operations, it becomes cool, if not cold, and its by strata of proliferated connective-tissue cells. The neurilemma cells had a neuroblastic function and proceeded to form new axis-cylinders and medullary sheaths. The new fibres in the distal segment had a longitudinal direction from the outset, whilst in the intermediate scar-tissue between the proximal and distal segments their direction was wildly irregular. But the mode of formation was the same in every case. Thirdly, in the distal segment of a divided nerve in which the cut ends had been left widely separated, according to the "central" theory, it being impossible for new fibres to reach the distal segment from the proximal, regeneration could not occur. But such was not the case. Regeneration could occur in the distal segment of a nerve even when widely separated from the proximal segment, and the process was exactly the same as that which occurred in a reunited distal segment. It commenced, however, at a later date (four or five weeks after division, instead of three weeks, as in a reunited nerve), and progressed more slowly. Moreover, the new fibres did not attain beyond the sinuous, beaded stage characteristic of incomplete maturity. If, however, such a distal segment, already partially regenerated, be sutured to the proximal segment the new fibres quickly attained to adult proportions, thus illustrating the common truth that physiological activity was necessary for anatomical perfection. Cases where the distal segment was in a condition of inflammatory sclerosis—such neuritis being usually of microbic origin—might exhibit great delay or even total inhibition of the regenerative process. The paper further dealt with nerve grafts, primary and secondary suture. The following subjects were suggested as a possible basis for discussion: (1) the mode of regeneration of peripheral nerve-tissue; (2) the absence of regeneration in the spinal cord and brain after injuries, and its association with the absence of neurilemma cells in the central nervous system; (3) the bearing of this on the neuron theory; (4) indications and contra-indications for operative interference; and (5) comparative advantages of various operations.

Dr. STEWART said that the facts above recorded had obviously an important bearing upon the views as to the architecture of the peripheral nervous system. For the last 11 years Waldeyer's neuron theory had practically held the field. According to this theory every axis-cylinder was a mere outgrowth from a nerve-cell, which outgrowth degenerated when cut off from the parent cell and could only regenerate by a process of down-growth from that cell. Regeneration ought, therefore, to be impossible in the distal segment of a divided nerve whose ends remained widely separated. He said that the neuron theory, so far, at any rate, as the peripheral nervous system was concerned, must be discarded. Finally, with regard to the clinical side of the question, if the views which had been maintained were correct then operative re-union of peripheral nerves ought to be attempted in almost every case. Operation might be contra-indicated, firstly, for anatomical reasons. Thus, for example, in a case of rupture of all the roots of the brachial plexus close to the vertebral column a surgeon might perhaps hesitate before diving down into a deep dissection at the root of the neck. Secondly, on account of the total loss of galvanic excitability in the paralysed muscles. Obviously it was not worth while re-uniting a motor nerve if there were no muscle-fibres left for it to innervate. But total disappearance of muscle-fibres in such cases was certainly less frequent than was commonly supposed. He had found some reaction to galvanism in the atrophied muscles in a case 16 years after division of the motor nerve.

Professor C. S. SHERRINGTON (Liverpool) said that the paper had suggested that a nerve-fibre was not a single nerve-cell process but a series of nerve-cells. He pointed out that in the central nervous system no regeneration of the fibres in the posterior column of the cord took place and yet they were but the direct continuation of a peripheral nerve. He referred to the fact that after excision of the posterior root ganglion in the lumbar region the root of the cauda equina 55 days after contained several well-marked fine fibres and he thought that these might be fibres which had regenerated. The electrical delay in the transmission of a current along the nerve supported the view that the nerve-fibre was made up of a series of cells which might act as electrical condensers. On the other hand, it was difficult to see why if the nerve was a series of cells it should degenerate when cut off from the nerve cell.

Dr. R. KENNEDY (Glasgow) said that these researches fully corroborated the results of his own investigations published by the Royal Society some five years ago. He referred to the view that the higher up a nerve was divided the longer was the time taken for the restoration of sensation. In his experience this had not been the case, and restoration of sensation had occurred as rapidly when the nerve was divided at one point as at another. The demonstration of newly-formed fibres in the peripheral segment which had been for some time totally separated from the central segment was first made by Philipeaux and Vulpian and had been confirmed by other observers. These young fibres, however, never attained maturity while unconnected with the central end, for the reason that they had remained without an opportunity of performing their function of the normal transmission of impulses from the nerve cell. Dr. Kennedy then referred to the healing of divided nerves and the restoration of the normal paths for the transmission of impulses. If the non-corresponding ends of nerve-fibres were brought into apposition and united the consequence was that the peripheral terminations became in connexion with centres in the central nervous system to whose innervation they did not by nature belong. To determine this question he divided the sciatic nerve in dogs and reunited it so that the fibres on the external aspect of the central end were in contact with those on the internal aspect of the peripheral end and *vice versâ*. The result was that function was completely restored and that as rapidly as in control animals in which the nerve had been divided and united as accurately as possible. A second series of experiments were then undertaken. The median, ulnar, and musculo-cutaneous nerves were divided above the elbow in dogs and the musculo-spiral was divided at the same point; the central end of the musculo-spiral was then attached by suture to the peripheral ends of the three nerves which supplied the flexor muscles and *vice versâ*. The result was that the animal in which these cross sutures were made regained coördination of movement perfectly. In these animals after coördinated function had been restored the condition of the cerebral cortical areas associated respectively with flexion and extension of the paw were examined by cortical stimulation and it was found that the relative positions of the two areas had become reversed. In conclusion, he referred to a case in which he had for facial spasm divided the facial nerve and united it to the spinal accessory, with the result that the face recovered its power of movement to a great extent, but that whenever the patient lifted the right arm a spasm of the face was produced.

Dr R. A. FLEMING (Edinburgh) said that he was still an upholder of the "central" view of regeneration, and he did not see why it should not be compatible with the finding of new formed fibres in the distal segment of a divided nerve. He referred to some experiments which he had performed in which he had ligatured the sciatic nerve in two places, and he had been able to demonstrate axis-cylinders both in the part between the two ligatures and also in the peripheral part 18 weeks after the operation. He asked Mr. Ballance and Dr. Stewart what method of fixing they had adopted and in what medium the sections had been cut. He did not agree with their observations that the fine nerve-fibres degenerated more slowly than the larger fibres, but he thought, on the contrary, that they degenerated more rapidly. He considered that the neurilemma nuclei acted as trophic agents to the axis-cylinder which they protected. It was therefore not improbable that regeneration should take place from these cells.

Mr. W. THORBURN (Manchester) referred to the fact that so little confusion occurred after union of peripheral nerves. He mentioned a case in which there was severe damage to the brachial plexus. The distal and proximal end of the nerves were united, but it was impossible to unite each nerve to its corresponding trunk. No confusion in movements, however, resulted.

The meeting, on the motion of Dr. F. W. MOTT, was then adjourned.

---

## MEDICAL SOCIETY OF LONDON.

### *Cardiac Pain.—Hypostatic Albuminuria of Splenic Origin*

A MEETING of this society was held on Feb. 24th, Dr. W. H. ALLCHIN, the President, being in the chair.

Dr. E. MARKHAM SKERRITT (Clifton) read a paper on Cardiac Pain. All pain was essentially conservative and protective, and heart pain tended to check strain that was a source of danger. Excluding from consideration the pain of acute disease and of neuralgia and neuritis, pain expressing the ulcer, or pylorectomy, gastro enterostomy, &c. The operation of gastro-enterostomy gives rest to the stomach and is, as a rule, a less severe measure than excision of the ulcer, which is therefore usually undertaken only when the patient is in good condition or when there is some doubt as to the innocence of the thickened and indurated tissues found at the time of operation.

Case 2 is an interesting one, especially as Mr. C. B Keetley[3] has drawn attention to the subject of pyloric stenosis so recently. No reference has been made here to any respiratory troubles following the act of swallowing the acid because no history of any such symptoms could be elicited from the patient. The reason why the pylorus is alone affected in these cases is difficult of explanation, but it seems possible that the irritation induced by the acid causes a violent contraction and immediate peristalsis of the stomach starting from the cardiac end, the part which is first touched by fluids entering from the œsophagus The effect of the peristalsis is to cause closure of the pylorus and, at the same time, to urge the gastric contents from left to right, so that the acid is in contact with the mucous membrane in the region of the pylorus for a much longer period of time than with any other. Nevertheless, it is strange that the acid does not cause ulceration of other parts of the stomach and of the œsophagus.

## LEEDS GENERAL INFIRMARY.

### A CASE OF INTUSSUSCEPTION; OPERATION; RECOVERY.

(Under the care of Mr. W. H. BROWN.)

THE most suitable treatment for irreducible intussusception cannot be said to be quite determined. Undoubtedly excision of the invagination with anastomosis of the two portions of bowel is theoretically the best, but a very large proportion of the children, on whom the operation has been performed, die. Attempts to establish an artificial anus or to short circuit the invaginated bowel have been made, but the mortality cannot be said to be less from these methods, and, moreover, the intussusception remains unrelieved. On the whole, therefore, simple excision of the affected portion of bowel with union of the two ends is probably the safest measure though the death-rate from shock and exhaustion will always remain high in these cases. For the notes of the case we are indebted to Mr. W. O. Greenwood, house surgeon.

A child, aged four years, was admitted into the Leeds General Infirmary on Jan 28th, 1902, with the usual symptoms of intussusception. The swelling could be felt stretching across the epigastrium; this was said to have existed for a month As some attempts at reduction had been made before admission Mr. W. H. Brown decided to operate at once. Under ether the abdomen was opened in the middle line by an incision about three inches long above the umbilicus. The tumour was brought out of the abdomen and the intussusception was found to consist of cæcum and ascending colon invaginated into the transverse colon. The reduction was easily effected with the exception of the last inch, which consisted of the cæcum and the vermiform appendix. This was so firmly impacted that no reasonable manipulation produced any effect. An incision was therefore made round the invaginated portion and this was excised; the parts removed comprised the vermiform appendix together with a circular portion of the cæcum of about the size of a two-shilling piece. The edges of the bowel were closed with silk sutures. The abdominal wound was treated in the usual manner. The child made an uneventful recovery.

*Remarks by* Mr. BROWN —I have had occasion to operate for the relief of intussusception upon many occasions, but this is the first time that I have been compelled to excise any portion of the intestine implicated. Had there been much distension or evidence of inflammation I should have made a fæcal fistula, for I hold very strongly the view that the right treatment for distended and inflamed intestine is to drain it and not to attempt immediate restoration of continuity. In the present instance these complications were absent and the child was fortunately spared the discomfort of a fæcal fistula.

ERRATUM.—In THE LANCET of Feb. 8th, p. 372, a case was reported in the Mirror of Hospital Practice which had been under the care of Dr. W. J. Collins at the London Temperance Hospital. In an editorial comment upon this case it was erroneously assumed that the duodenal ulcer, as well as the gastric ulcer, had perforated. As this was not so of course no idea of any secondary laparotomy could arise.

# Medical Societies.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

### *Discussion on the Regeneration of Peripheral Nerves.*

A MEETING of this society was held on Feb. 25th, Sir THOMAS BARLOW, Bart, being in the chair.

Mr. CHARLES A BALLANCE and Dr. J. PURVES STEWART communicated a paper on the Regeneration of Peripheral Nerves. The fact had long been admitted that regeneration could occur in peripheral nerves if their opposing ends, previously divided, were brought into apposition. As to the process whereby this regeneration was accomplished, however, there had been two schools of opinion, which might be termed the "central" and "peripheral" respectively. According to the "central" school (supported by Renvier, Waller, His, Vanlair, Stroebe, Howell and Huber, and others), the new nerve-fibres which occurred in the distal segment of a reunited nerve-trunk were formed by a process of down growth from the proximal segment, and threaded their way gradually along the neurilemma sheaths of the distal segment, already rendered empty by the degeneration of the old axis-cylinders and medullary sheaths The new fibres were thereby guided ultimately to the periphery. The "peripheral" doctrine, hitherto a less popular one (amongst the chief supporters of which might be mentioned Tizzoni, Cattani, Bethe, Kennedy, and Galeotti and Levi), taught that the new nerve-fibres were formed locally in the distal segment from pre-existing elements there. This, in their opinion, was the correct view. If a peripheral nerve were cut across certain changes occurred in the lower part of the proximal segment and throughout the entire extent of the distal segment. These changes consisted of: (1) degeneration, and (2) regeneration The two processes overlapped in point of time; regenerative changes commenced before degeneration was complete. Degenerative changes affected the lower end of the proximal segment and the whole extent of the distal segment. They occurred simultaneously in these parts and did not spread from the centre to the periphery or *vice versâ*. Changes in the axis-cylinders and medullary sheaths were next described. The changes of regeneration were then dealt with, firstly in the proximal segment of a divided nerve which had not been reunited These consisted in the formation of the well-known so-called "end-bulb"—a dense, club-shaped swelling in which were numerous young nerve-fibres, coiled and intertwisted in all directions, embedded in fibrous tissue. According to the "central" theory of nerve regeneration these new fibres were to be regarded as outgrowths from the central end which, unable to find their way into the distal segment, had turned back on themselves in a futile manner like the apex of a fountain This, however, was not so. Every new fibre of the permanent end-bulb was laid down in separate short links, each in apposition to a neurilemma cell, thickest near the nucleus of the cell and tailing off at each extremity. These short lengths of young nerve-fibres were at first separated by some distance from the ends of the central axis cylinders. The end-bulb was not formed by a downgrowth and recurving of axis-cylinders, but by the development of new fibres in a structure which Mr. Ballance and Dr Stewart had named the "primitive end-bulb"—a mop like protuberance which was formed immediately the nerve trunk was divided, the result of the curling back upon themselves of the divided nerve fibres. In the "primitive end-bulb" degeneration occurred as above described and was followed by regeneration whereby the proliferated neurilemma cells secreted small islands of axis-cylinders and medullary sheaths These islands later overlapped in an imbricating fashion and ultimately fused together to form a long nerve-fibre continuous with one of the nerve-fibres of the proximal segment above [illegible] in the distal segment of a divided nerve, reunit[illegible] proximal segment by sutures, the proliferated n[illegible] cells arranged themselves in longitudinal columns the most frequent cause of angina pectoris. He referred to the term "cramp" which had been used in explanation of the condition angina pectoris and considered that it was a term inapplicable to cardiac muscle as the heart muscle did not undergo such contraction.—Dr. A. MORISON said that the term "cramp" was a useful term to use in description of certain cardiac conditions. In some cases of angina pectoris which had terminated fatally a condition of fragmentation of the muscle had been found, and he considered that this might indicate rupture of the fibres during an attack. With regard to the localisation of pain, he thought that they might assume that it originated in the heart itself. He considered that attacks of angina pectoris were frequent in cases of aortic regurgitation, but they also occurred in cases of aortic stenosis, although this latter lesion was of rare occurrence. He suggested that the pain of angina pectoris might be due to irritation of the nerves which were so abundant around the aortic orifice.—Dr. F. PARKES WEBER said that both cardiac muscle and unstriped muscle underwent "cramp." He thought that localised cramp might take place in the heart just as localised cramp occurred in the muscles of the limbs. He pointed out that the tissue-effects of waste products were produced by an insufficient blood-supply to wash out these products.—Dr. W. PASTEUR thought that cardiac pain was an uncommon manifestation of heart disease, but that it most frequently occurred in cases of degeneration of the cardiac muscle.—Dr. H. D. ROLLESTON suggested that if a localised "cramp" occurred it might effect the musculi papillares. He agreed with the last speaker in considering that cases of acute cardiac pain were rare and were most frequently associated with aortic disease. With regard to angina in young people it was difficult to diagnose and he quoted the case of a young man who had attacks of pain which he considered to be functional. The man died suddenly and atheroma of the vessels at the base of the heart was found. He doubted if fragmentation of the cardiac muscle could be regarded as evidence of "cramp," for the contraction of rigor mortis was much more severe and might produce such fragmentation.—Dr. H. CAMPBELL POPE said that the pain of angina pectoris was not infrequently referred to the right side of the chest and also to the left axilla. He referred to a case of sudden death in which there was atheroma of the coronary vessels, but there had been no angina. He thought that tea was a frequent cause of attacks of cardiac pain.—Dr. SKERRITT replied.

---

[3] THE LANCET, Nov. 16th, 1901, p. 1323.

Dr. ROLLESTON read a note on Hypostatic Albuminuria of Splenic Origin. The paper is published in full on page 585.—Dr. SANSOM said that "postural albuminuria" had been described by Teissier. He suggested that it was of importance to eliminate the possibility of the albuminuria being due to some other cause than the mechanical one of pressure of the spleen on the left renal vein, for the albuminuria might be of malarial origin. He did not consider "postural albuminuria" to be of serious import.—Dr. ALLCHIN doubted if the enlarged spleen could press on the left renal vein, but the point could easily be decided by post-mortem observation.—Dr. ROLLESTON, in reply, pointed out that had the albuminuria in his case been due to a malarial nephritis it was improbable that it would have disappeared with the change of position.

# BRITISH GYNÆCOLOGICAL SOCIETY.

### *Exhibition of Instruments and Specimens.—Presidential Address.*

A MEETING of this society was held on Feb. 14th, Dr. J. HALLIDAY CROOM, the President, being in the chair.

Dr. F. WINSON RAMSAY exhibited a series of perforated, hollow, metal Uterine Dilators. He maintained that their use was not attended by the piston-like action of otherwise similar dilators, and that their introduction was consequently much more easy and free from any risk of forcing any deleterious matter into the Fallopian tubes.

Mr. R. T. A. O'CALLAGHAN showed Submucous and Intraligamentary Myomata and a Cancerous Uterus, all of which had been removed by abdominal hysterectomy.

Dr. H. MACNAUGHTON-JONES exhibited the following:—1. Professor Bossi's Instrument for Rapid Dilatation of the Os and Cervix Uteri in cases of Eclampsia and Contracted Pelvis. He had seen it applied for the first time in October, 1901, when visiting Professor Leopold's clinic in Dresden. The illustrations (Figs. 1, 2, 3, and 4) show that the instrument has a special curve and that its branches or blades are grooved externally so as to prevent them from slipping in the cervical canal. By an arrangement of pivots the three branches, when the wheel handle is rotated, open simultaneously to an extent of ten centimetres, and the degree of separation is indicated on a quadrant. In the case in which Dr. Macnaughton-Jones saw Professor Leopold apply the dilator the pelvis was rachitic and had an internal conjugate diameter of seven centimetres, and there was a double promontory. In some 20 minutes the dilatation was sufficiently complete to admit of the perforation of the head and the application of the cephalotribe. The case was an exceptionally difficult one, but delivery was completed within another 20 minutes. In a number of cases reported by Professor Bossi, Dr. Giuseppe Zirolia, and Dr. G. de Paoli of the University of Genoa, dilatation to eight centimetres was effected within 20 minutes in cases of eclampsia, and delivery was then successfully completed by Simpson's forceps. The instrument had also been used in cases where dilatation by other methods for the induction of premature labour had failed. It was claimed for it that by its means rapid dilatation could be obtained within a period of from 15 to 30 or 35 minutes without interfering with the integrity of the cervix

Closed end of dilator, the guards being removed. This enables the operator to dilate the cervix to a given extent when the four grooved guards can be fixed on the ends.

the overloading of the heart occurred in all degrees of intensity, there being no line of demarcation, clinical or pathological, between one extreme and the other. Heart pain due to the disturbance of the balance between power and work might occur (1) when the heart was normal but work was in excess; or (2) when the heart was diseased: (*a*) primarily in its valves, or (*b*) primarily in its walls Pain in the normal heart from overwork might be induced by over-exertion, such as hard riding when "out of condition"; it was not pronounced and it quickly passed off with rest. It was also met with in "vaso-motor angina," a neurosis of the cardio-vascular system increasing the peripheral resistance to the circulation by causing spasmodic contraction of the vessels and hence painful embarrassment of the heart's action, in some cases increased by anæmia of the cardiac muscle due to coincident contraction of the coronary vessels. Vaso-motor angina occurred mostly in early adult life and about the climacteric period in women of neurotic type and in men from excess in alcohol or tobacco. It might be induced by cold, by exertion attended with excitement, and especially by emotional disturbance. Certain blood conditions, especially the presence of uric acid, the absorption of ptomaines from the bowel, and the action of some drugs of the digitalis class, increased the general blood-pressure and therefore made it easier for the contraction of the peripheral vessels to embarrass the heart. Fatigue of the heart as a muscle attended its action, and Dr. Gaskell had shown that fatigue of muscle produced a tendency to cramps and that accumulation of the products of muscle waste induced acidity which caused paralysis. The symptoms of vaso-motor angina came on suddenly, with acute pain and oppression at the heart, palpitation, and dyspnœa, the pulse being small and quick, usually with increased tension. The latter quickly relaxed and the patient passed into a restless condition. Sir R. Douglas Powell stated that marked angina of this type was not common and the prognosis was good. Dr. Skerritt had met with it in gouty cases and also at the climacteric period, but not in young adults; and in his experience the climacteric cases usually did badly, going on to permanent cardio-vascular changes. In the second class the element disturbing the balance between work and power was disease of the heart, which might occur primarily in the valves or in its walls. Valvular disease, as a whole, was not an important cause of angina. Authorities agreed that pain was most often met with in disease of the aortic orifice. In Dr. Skerritt's experience the valvular lesion in which anginal symptoms were met with in a marked form was aortic regurgitation; but other observers were not of the same opinion, the late Dr. Walsh, for example, holding that aortic stenosis was the chief valvular cause of pain. Aortic stenosis, however (which might occur in all degrees), was the valvular lesion in which compensation by hypertrophy was most complete, maintaining the balance between work and power in such a way that heart distress was least likely to arise; while in aortic regurgitation the conditions were such as to tax the ventricle severely, causing marked dilatation and hypertrophy, and later degeneration in the cardiac wall—conditions most calculated to produce distress and pain of the heart. Degenerative changes in the heart wall were of by far the greatest importance in the causation of angina pectoris They were mostly secondary to narrowing of the coronary arteries by atheroma and calcification; and their effect was to weaken the heart as a muscle and to favour the occurrence of paralysis. When atheroma of the coronary arteries was marked the balance between heart-power and work was proportionately disturbed, so that the enfeebled organ could no longer carry on the work of the normal circulation without signs of distress. Much greater was this distress when the enfeebled heart was opposed by increased arterial tension, due to chronic renal disease or to the vascular degeneration of age. The type of cardiac action then indicated the danger which threatened; the notable feature of the pulse was its high tension; the short and toneless first sound was hurriedly followed by a ringing aortic sound, the ventricle being hardly able to hold its own until the strain was taken off by the closure of the aortic valves, and the patient plainly lived on the brink of a precipice. Various theories had been advanced as to the pathology of angina pectoris: that it was a neuralgia or a neuritis of the cardiac nerves and that it was due to the stretching of the nerves in the heart wall, and that it had its seat in the aorta and was caused by aortitis. Dr. Osler had drawn attention to the theory which Allan Burns advanced in 1809, that the condition was one of transient ischæmia of the heart muscle from disease or spasm of the coronary arteries. In "intermittent claudication," met with in the horse and also in man, transient paraplegia and spasm might follow exertion, owing to thrombosis of the abdominal aorta or the iliac arteries; the collateral circulation, ample when the limbs were at rest, being insufficient for active movement, relative ischæmia of muscle was induced with loss of power, which passed off with rest. A heart with calcified coronary arteries was in an analogous state and any extra exertion might cause ischæmia and spasm of the heart. Dr. Parkes Weber pointed out that the cramp pains and loss of power in muscle were both due to the accumulation of waste products and that they were more easily caused if the vascular supply was not enough to flush properly the muscle when in action; that the lymph fluid of all tissues at rest was alkaline; and that the activity of muscle was always accompanied by dilatation of its blood-vessels, brought about by the lessened alkalinity of the lymph fluid of the tissue during its activity, which relaxed their muscular coats. When the vessels were altered by disease the flushing of the tissues with blood while in action was interfered with, and hence the phenomena of paralysis and pain met with in angina pectoris. Time failed for the discussion of the treatment of cardiac pain except to point out that the balance between work and power might be restored (1) by increasing the power of the heart, or (2) by lessening its work. Practically the latter was usually the easier, and hence the diminution of vascular tension by means of the vaso-dilator remedies.—Dr. E. SYMES THOMPSON regretted that the paper had not dealt with the treatment of cardiac pain. He considered that functional disease more frequently gave rise to pain than organic lesions of the heart muscle or valves, and he thought that the heart was very liable to be put "out of gear" by emotional causes. In hysterical and hypochondriacal subjects the pain was often dependent upon causes which under other conditions of the individual gave rise to no pain.—Dr. A. E SANSOM said that the word "functional" as applied to these affections of the heart should be discarded, as it was probable that all had some organic origin. The vaso motor angina of Nothnagel gave rise rather to a sense of discomfort than to actual pain, and such conditions were the outcome of exertion. He considered that there were but few cases in which cardiac pain was persistent; the pain was due to dilatation of the right side of the heart, but the heart soon accommodated itself to its altered conditions and the pain passed off. He had seen great relief from cardiac pain obtained from regulated exercises He said that the greater number of cases of cardiac pain were due to neuralgia and to neuritis which might be of gouty origin. These he designated the extrinsic causes. He had for many years considered that true angina pectoris was always associated with thickened arteries, but he had somewhat altered his views on this point, for he had found that cases occurred in which there were neither hypertrophy of the heart nor thickening of the vessels. In one such patient there was a condition of anuria and probably also a contraction of the arterioles of the heart. The lesion of the valves most commonly associated with angina was aortic regurgitation and not aortic stenosis, and in aortic regurgitation there was a moment of intense strain for a very limited period of time on the heart wall. In regard to treatment he considered that phenacetin and antipyrin were to be preferred to opiates The use of vaso-dilators was as liable to abuse as were drugs with a sedative action. He had seen but little benefit from the use of nitrites.—Dr. F. DE HAVILLAND HALL related a case of a man between 50 and 60 years of age who had attacks of pain of the nature of angina pectoris accompanied by faintness. In this case nitro-glycerine did but little good, but the patient was benefited by a blue pill and a saline mixture. He continued to have attacks of pain for some years, but on one occasion he had a typical attack of hepatic colic, and from that time he suffered no more from the attacks of pain which had been considered anginal. He (Dr. Hall) thought that hepatic colic was not infrequently mistaken for angina pectoris.—The PRESIDENT said that it was a matter of great interest how far the pain was in the heart itself. In most cases in which there was disease of the heart the pain radiated over a considerable area and especially down the left arm. He pointed out that visceral disease gave rise to but little pain until the serous coat was affected. He thought that actual degeneration of the wall of the heart was minds of many to revolutionise, their ideas of the structural requirements for the treatment of active mental disease. Seclusion rooms and single rooms of all kinds, formerly regarded as indispensable for the excited and restless, were now found to be required only in a few exceptional cases. Almost all cases of acute insanity could be more efficiently treated in associated dormitories than in single rooms. Another recent development had brought wards for mental diseases more into line with ordinary hospital wards—that was the introduction of nursing by women into the male wards of asylums. Sir John Sibbald attached great importance to the circumstance that it tended to foster the feeling amongst the patients that they were from first to last regarded as suffering from illness which required medical treatment. As regarded the defects which existed in the present clinical teaching, there were two. The first was that the seats of teaching at Morningside and at Larbert were too distant from the medical schools. To make the teaching really efficient it ought to be given in the immediate neighbourhood of the schools, and in Germany every university now had its psychiatrical clinique close to the medical school. The example set by Germany was being followed by the other continental nations, and the United Kingdom might now be said to stand alone in being without such provision. The other defect was even more important. The clinical teaching should supply knowledge which would be useful to the student when he entered on general practice. But at present the only clinical teaching was given in lunatic asylums and consequently the only patients whom the student saw were those whom the general practitioner was not called upon to treat. Under present arrangements the ordinary medical student received no clinical teaching as to the treatment of the incipient and the transitory phases of mental disease. It was in the treatment of these phases of mental disease that he would in after life find himself in the presence of one of his most serious responsibilities, and it was only by the establishment of such wards as were proposed that he could be duly equipped for the discharge of these responsibilities, and Sir John Sibbald concluded by strongly urging the provision of such wards.

The MASTER OF POLWARTH, Chairman of the General Board of Lunacy, said that it had been the policy of the Board of Lunacy to see that not only the bare legal requirements were carried out, but also to encourage every new experiment which seemed likely to benefit those affected by mental disease. From this point of view the proposed scheme had a very particular interest, and he earnestly hoped that steps would be taken to carry it out and to keep Scotland in the forefront.

Sir JOHN BATTY TUKE said that for the last 20 years he had tried on every available occasion to lay before the public the advantages to be gained by the hospital treatment of acute mental diseases in the general hospitals of the country. The proposed scheme would reduce the number of lunatics and would exercise a great educational influence. The ratepayer was burdened by having to provide for the wants of the chronic lunatic, while little or nothing was done for the acutely diseased; nothing was done to avert the manufacture of the chronic lunatic. If general paralytics and epileptics were excluded and if they treated cases in the earlier stages they would get 70 per cent. of recoveries. The increase in insanity was not amongst the upper classes, where early and efficient treatment was obtained, but in the lower classes which could not get this. This proposal would tend to break down popular misconception by treating general and mental disease in the same hospital and might in time also affect legislation, especially in England. As regarded education, a general asylum was the worst possible place to learn about mental diseases and the early treatment of such cases by the general practitioner was of the greatest importance. He urged upon the managers of the Edinburgh Royal Infirmary the extreme importance of entertaining such a scheme as that proposed.

Dr. J. O. AFFLECK said that his experience as an infirmary physician had shown that frequently patients were brought suffering from mental disorders, due, perhaps, in many cases to bodily disease, and such cases would, he thought, be more beneficially treated in hospital wards than in an asylum. He admitted that there were serious practical difficulties, but he thought that these could be overcome by the managers.

Dr. J. S. CLOUSTON said that during the last two years 900 cases had been admitted to Morningside Asylum, and of these 80 were discharged recovered within from six to eight weeks and about 160 within two and a half months. These cases could have been treated in the infirmary and many patients who could be treated there could complete their convalescence at home. He thought that the parish council might arrange with the managers of the Royal Infirmary to pay, say, £50 for each patient sent to such wards and in this way save the cost of building two of the blocks at the new asylum. The ward treatment of such incipient cases would prevent the rates being increased by the prevention of such cases becoming chronic. Such a scheme would afford the poorer classes similar advantages to those which the rich now possessed and would give them the same chances of recovery. It was part of the original design of the infirmary to treat mental disease.

After Dr. ALEXANDER BRUCE and Dr. URQUHART had spoken, Mr. J. CARSWELL, adviser in lunacy to the Glasgow Parish Council, said that in Glasgow they hoped to have the first psychiatrical clinique in Scotland. In connexion with one of the poorhouse hospitals a mental block was being built for 50 patients, where they would be treated on hospital lines. Of 212 patients admitted last year 28 were removed to asylums, 10 died, 167 were discharged recovered, and seven remained under treatment at the end of the year.

Dr. G. R. WILSON of Mavisbank, Dr. SLOAN, and Dr. H. M. CHURCH having spoken, Sir JOHN BATTY TUKE finally moved :—

> That this meeting urges strongly on the managers of the Royal Infirmary the propriety of seriously considering the expediency of providing wards within or in the immediate vicinity of the institution for the treatment of incipient, transient, and recent cases of insanity.

The MASTER OF POLWARTH seconded this motion, which was adopted unanimously.

## SECTION OF OBSTETRICS.

### *Laparotomy for Ovarian Cystoma.—Induction of Labour followed by Enucleation of Tumour.*

A MEETING of this section was held on Jan. 7th, Dr. W. J. SMYLY being in the chair.

Dr. ALFRED J. SMITH read notes on Laparotomy for an Ovarian Cystoma which had ruptured six hours before removal, the specimen being also shown. Ovarian cysts, he said, might spontaneously rupture into the peritoneal cavity or into some neighbouring organs. The effect on the patient, of course, depended on the character of such a cyst and of its contents. Innocent ovarian tumours generally produced only trifling symptoms, some pain and profuse diuresis being the chief disturbance. Dr. Smith's case, however, showed that grave symptoms and profound shock might follow spontaneous rupture of a common multilocular glandular cystoma. In the result the patient made a good recovery.—Dr. SMYLY stated that he had found rupture of ovarian cysts to be caused by tapping, particularly if the operation had been repeated. In one case, after laparotomy had been performed, the contents of the cystoma escaped into the peritoneal cavity, and so much time was occupied by wiping the matter from the coils of intestines that the patient collapsed. Massage might also cause the rupture of such tumours. He had seen the daily practice of massage diminish an ovarian cystoma to the vanishing point—the tumour had been ruptured and its contents rubbed out of the sac. Even gentle palpation had caused rupture. In the Adelaide Hospital, whilst a tumour was being very carefully palpated it burst and he at once performed laparotomy. He found a malignant cystic tumour which he removed; the patient recovered from the operation well, but the disease recurred some months afterwards.

Dr. F. W. KIDD read notes on a case of Induction of Labour followed by Enucleation of a Fibroid Tumour in the Cervix. He had seen the patient when she was a little over four months pregnant and he thought that it would be quite possible to deliver her without operating provided—(1) that the tumour did not enlarge during further gestation; (2) that she came to Dublin again three months later; and (3) that he was successful in inducing labour. She returned at the appointed time, and as she had a large roomy pelvis and vagina it was resolved to induce labour and to attempt delivery. Labour was brought on by the introduction of a bougie between the membranes and the uterus. When she had been about 34 hours in or causing any injury to the presenting part. Before resorting to the use of the dilator the genitalia must be carefully disinfected, and during its application there must be complete narcosis.[1] 2 A complete Vertical Section of a Carcinomatous Uterus in the third month of pregnancy. The section, which was transparent, was that of a uterus removed in Professor Bumm's clinic in Halle. It had been treated with picric acid, alcohol, and colloidine, cut with a large microtome, and stained with carmine. 3. Professor Zweifel's new Broad Ligament Pressure Forceps for use in Vaginal and Abdominal Hysterectomy. 4 Some photographic card specimens of Ectopic Gestation, and specimens of Myoma with Deciduoma Malignum and Elephantiasis Vulvæ, taken in Professor Sanger's clinic in Prague.

The **PRESIDENT** then delivered his Inaugural Address. He pointed out the great advance that had been made in obstetrics since the beginning of the last century—an advance to be ascribed to the introduction of anæsthesia and antisepsis. Though no absolutely new instrument or operation had been devised, symphysiotomy had been revived, and unquestionably it had a future before it; the mortality from Cæsarean section was insignificant when compared with earlier results. Owing to improved knowledge of the mechanism of labour and the earlier recognition of pelvic deformities, operations involving the death of the fœtus might often be avoided by the use of axis traction forceps or by performing Cæsarean section before the patient had been exhausted by futile attempts at delivery. Eclampsia was the solitary exception in which little improvement had taken place in treatment Indiscriminate removal of the ovaries for all sorts of inflammatory trouble had ceased, but surgical interference was perfectly justifiable in cases in which complete rest—mental, bodily, and sexual—was impossible, even though condition together with local measures might effect a cure, provided the preservation of the reproductive powers was not essential. Non-interference in ovarian tumours, pelvic suppurations, and extra-uterine pregnancy meant certain ill-health and almost certain death In fibroid tumours the position was widely different; though pressure symptoms might render them dangerous they were rarely in themselves fatal. Rapidity in growth, recrudescence in later life, or degenerative changes were more important indications for interference than hæmorrhage. But a woman was not an appropriate subject for surgical interference merely because she had one or more fibroid tumours; operation for such might be expedient to add to her comfort, but it was seldom required for the saving of her life. Cancer of the uterus was enormously prevalent and was unhappily becoming more so. The vexed question of its ætiology did not as yet affect the question of its surgical treatment, in regard to which the desiderata were early recognition and some efficient method of dealing with the lymphatic glands and vessels No such method had yet been discovered, and in but few cases patients applied for treatment in hospitals in time for successful operation. So long as the uterus was of moderate size and fairly mobile, the bladder unaffected, and there was no evidence that the glands were involved, operation, especially when the disease was primary and limited to the fundus, was desirable, and vaginal hysterectomy was the most rapid and satisfactory method. But statistics had shown that when the disease was advanced life was not prolonged, neither was suffering alleviated, by operation, and interference should therefore be declined On the whole, the results of the surgical treatment of uterine cancer were by no means brilliant, and it seemed possible, and even likely, that the triumph of successfully combating this foe would be medical rather than surgical, by the discovery and destruction of its exciting cause

# EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

## *The Treatment and Teaching of Incipient and Transient Mental Disorders in the Royal Infirmary of Edinburgh.*

A SPECIAL meeting of this society was held on Feb 19th under the presidency of Professor T. R. FRASER to discuss "The Treatment and Teaching of Incipient and Transient Mental Disorders in the Royal Infirmary of Edinburgh." The meeting was a large and representative one, and most of the managers of the Royal Infirmary were present.

The **PRESIDENT**, in opening the discussion, said that there were two great problems to be faced: firstly, an accurate definition of those kinds of cases which could be most favourably treated in a hospital ward as contrasted with an asylum; and secondly, what accommodation would be required; how many cases could be so treated in this way and how far this could be carried out in the Royal Infirmary; to what extent could the financial resources of that institution be drawn upon; and how far such treatment would benefit patients or the general public.

**SIR JOHN SIBBALD** then read a paper, which he said had been written at the suggestion of Dr. T. S. Clouston and Dr. John Macpherson. The chief object was to elicit the views of the meeting in regard to what was deemed to be an important defect in the present arrangements for the treatment of mental disease and for giving clinical instruction in regard to it. He indicated that this defect might be best remedied by the establishment of wards in the Edinburgh Royal Infirmary for the treatment of incipient and transitory mental disorders Little needed to be said to show that the wards proposed would be useful from the charitable point of view, as patients in the early stages of mental disorder were at present almost neglected; general hospitals or lunatic asylums were the only institutions into which such cases might be received, but cases of mental disorder were usually excluded from the former and the cases which he had in view had not arrived at the stage which made relegation to an asylum either necessary or justifiable The considerations which seemed to show that hospital treatment in the Royal Infirmary would benefit such patients most might be summarised as follows: (1) in the treatment of this class of cases the special arrangements which distinguished asylums would not be essential; (2) everything which would suggest the idea of an asylum would be open to objection as tending to prevent patients and their friends from availing themselves of the benefits of these wards; (3) the wards would not differ appreciably from the wards of a general hospital; (4) it would be of the utmost importance that they should form part of an institution the purpose of which was recognised to be the cure of persons suffering from illness in order to stamp the wards with their true character in the eyes of the public; and (5) an out-patient department should, if possible, be attached to the wards, and such a department would be more resorted to by patients if it were connected with the infirmary than if it were connected with an institution devoted solely to the treatment of mental disease. It was necessary to bear in mind that it was not proposed that patients should be kept in these wards for long periods. Nor was it proposed that patients should be compulsorily detained in the wards, except in the sense that the wards of general hospitals sometimes were employed thus for patients suffering from ordinary diseases The limitation of the period of residence was important for this reason amongst others—that it helped to define the character of the cases to be treated. Sir John Sibbald would be satisfied with a limit of six weeks. Before the end of that time, if death or recovery had not taken place, it would in most cases have become evident that asylum treatment was inevitable In reference to the arrangements of wards the trend of medical opinion as to the treatment of mental disorders in the early stages must be kept in mind. An opinion had been steadily moving towards the adoption of methods resembling those employed in the treatment of bodily disease The main indications for treatment, especially for the incipient and transient phases of mental disorder, whether characterised by melancholic depression, maniacal excitement, mental confusion, or stupor, were to obtain repose, to induce cessation of effort both mental and bodily, and to restore the nutritive processes to healthy action. Such treatment as that advocated by Weir Mitchell for neurasthenia was equally applicable to the early stages of mental disorders and ought to be regarded as an essential element in the cure of a majority of such cases. Consideration of the improved system of nursing could not be omitted. This had developed *pari passu* with the bed treatment. One result of this had been to modify, and in the tendency, the disease was diagnosed as purely vaso-motor in origin. Within a year, however, a faint but distinct double aortic murmur was detected. The aortic regurgitation was never very great, as the left ventricle showed hardly any enlargement, nor was the pulse collapsing. The pulse *tracing* showed an anacrotic wave. The angina was much improved by rest and treatment, but the patient was never free from dyspeptic symptoms and persistent neuralgia of the right side of the head. Death occurred from heart failure five years from the onset of the symptoms. It was thought that there was sclerotic thickening of the aortic valves and orifices of the coronary arteries—probably of a syphilitic nature. Allusion was made to "pseudo-angina pectoris," an affection generally affecting women and showing itself before middle life and not as a rule fatal. The cases in which no coarse cardiac lesion could be detected often were, however, more grave than those in which there was obvious cardiac disease, for angina pectoris might be the only symptom of a serious condition, such as progressive occlusion of the coronary arteries.—The President, Dr. Handford, Dr. Tresidder, and Dr. F. H. Jacob discussed the subject.

Contributo alla scelta dell' intervento nei Casi Gravi di Eclampsia, Dr. G. de Paoli, ibid.

**Cardiff Medical Society.** — The ordinary monthly meeting of this society was held in the lecture room of the Cardiff and County Public Health Laboratory on Feb. 6th, Dr. A. P. Fiddian being in the chair.—Mr. W. Hughes, the medical superintendent of the *Hamadryad* hospital ship, showed two cases of beri-beri from the "ship," and described the appearances, which were of the characteristic type. There were four cases in all at the *Hamadryad*.—Dr. E. Walford said that the cases arrived in the Norwegian barque *Collingwood,* which voyaged from Capetown to Rangoon, and thence to Queenstown and Cardiff. The disease appeared about six weeks after leaving Rangoon. It was suggested that it was due to shutting ports and heating the forecastle when the ship got into colder climates. The symptoms very much resembled those produced by arsenical poisoning. Arsenic had been found in the intestinal organs in some cases.—Dr. Swale Vincent suggested that the blood should be tested for cholin, set free by the degeneration of the nervous tissues.—Dr. W. G. Savage stated that his examination of the ship's provisions for arsenic had given a negative result. —Mr. W. B. C. Treasure described two cases which he had seen on a Chinese ship two months previously, in each of which the leading symptom was œdema.—Dr Savage read a paper on the Value of the Leucocyte Count and the Method of their Enumeration. He gave a brief account of the number and varieties of the leucocytes in health and disease and pointed out how their examination and the determination of the relative proportions of the different varieties were of great value in diagnosis and in prognosis. The conditions leading to an increase of white corpuscles in the blood were considered and the clinical significance of the leucocyte changes was insisted on. For the enumeration of the leucocytes the method advocated was Stengel's, somewhat modified, by means of which the red and white corpuscles could be counted in the same blood preparation. Full details were given.—Dr. Savage then read a paper entitled "Notes on the Serum Reaction of Typhoid Fever." The nature of the reaction was explained and the method of production of the agglutinating substances was touched upon. The microscopic and sedimentation methods of performing the reaction were demonstrated and the chief practical considerations, such as when the reaction first develops, its trustworthiness, possible fallacies, and causes of error, were explained.—A discussion followed each of these papers.—The meeting then adjourned to the bacteriological laboratory where an interesting exhibition of bacteriological, microscopical, and pathological specimens, arranged by Dr. Mitchell Stevens and Dr. Savage, was inspected.

**Plaistow and Canning Town Medical Society.** —A meeting of this society was held on Feb. 12th.—The Annual Report, which showed the steady and continued progress of the society, was read and passed.—Dr. T. D. Lister read a paper on Some Disorders of Adolescence in Women. He referred briefly to the physiology of growth and development in the woman and gave a list of the ailments which were most commonly found at this age. Speaking of chlorosis and the secondary anæmias, he urged the importance of differentiating them. He drew attention to the anæmia of overcrowding, both in dwellings and employments. Anæmia was frequently due to an excess of developmental energy beyond the hæmogenetic power of the patient. In the use of drugs iron was essential, and he considered that cow's milk was a very valuable restorative and stimulus to cell changes on account of its earthy salts, apart from its action as a food. He ascribed no value to alcoholic drinks containing traces of iron, nor any advantage to organic compounds of iron, which were in his opinion inferior to properly selected iron salts. In heart disease symptoms and not physical signs were the indications for treatment. Hysterical patients were often spoilt children. In neurasthenia, which was often akin to developmental anæmia, nerve stimulants should be avoided. Constipation was most often due to neglect and the abuse of purgatives was condemned. Dyspepsia was chiefly hyperacid or atonic. Hæmatemesis arose from vascular malnutrition in chlorosis as well as from gastric ulcer.—A short discussion followed.—Various patients were shown by Mr. Jordan Harvey and Dr. E. Hay. —The following gentlemen were elected office-bearers for the year.—President: Mr. Percy Rose. Vice-President: Mr. H. S. Beadles. Honorary treasurer: Dr. W. C. Taylor. Honorary secretaries: Dr. E. P. McLoughlin and Dr. Hay.

**Glasgow Southern Medical Society.**—A meeting of this society was held on Feb 20th, Dr. John Stewart, the President, being in the chair.—Dr. E. A. Gibson read a paper on Notes of Three Cases of Abdominal Section and showed Specimens. The cases were (1) an interstitial fibroid; (2) a large fibroid with accessory growths; and (3) dilated and hypertrophied Fallopian tubes. In the course of his notes on these three cases Dr. Gibson emphasised the following points as worthy of special mention. All the cases happened in unmarried women; in each the onset was sudden, with symptoms pointing to obstruction and retention of urine and absence in each of hæmorrhage notwithstanding the large size of the uterine cavity.—Dr. Andrew Wilson read a note on the Prevention and Treatment of Conjunctivitis in the New-born. In introducing the subject Dr. Wilson briefly reviewed the history of the disease and referred to the detection of the *gonococcus* by staining with methylene-blue. He detailed in a thorough manner the steps to be followed in the way of prophylaxis. The disease having been acquired the most important point in the treatment was the thorough cleansing of the eyes every hour, a matter of more moment than the use of any special antiseptic or astringent. If under daily direct medical supervision he recommended the daily application of 20 per cent solution of protargol, but if the patient was seen at the dispensary he gave a 10 per cent. solution to be dropped into the eyes by the mother three times daily. He thought that protargol had greater penetrating power than nitrate of silver and did not stain the lids even when used continuously. Dr. Wilson also indicated the importance of notification of such cases of disease of the eye, recommending it as a practical measure of which a modified form obtains in Germany.—Both papers gave rise to interesting discussions and at the close Dr. Gibson and Dr. Wilson received the thanks of the society for their contributions.

**Forfarshire Medical Association.**—A meeting of this society was held on Feb. 6th, Professor D. MacEwan, the President, being in the chair.—The President showed a girl on whom he had performed Astragalectomy for neglected Talipes Equinus with good results. He also gave details of a case of Extroversion of the Bladder which he had treated with lateral flaps with the result that the upper opening formed above the flaps was now practically closed. The bladder now had an anterior wall and the urine was escaping through an opening at the lower part.—Professor A. M. Stalker read notes of two cases showing Peculiar Mental Symptoms of Sudden Onset—loss of memory followed by coma, terminating in recovery, but with absolute inability to recall anything since the onset of the attack. He was inclined to the view that these and similar instances which he had seen arose from toxæmia. There was in neither of these cases any history of accident or any albuminuria.—Dr. A. R. Urquhart (Perth) referred to the medico-legal aspect of such cases and mentioned two cases of imposture resembling these. He was of opinion that one of Professor Stalker's cases might have been due to premature senility.—Dr. Urquhart then read a paper on Status Epilepticus, in which he stated that during 20 years at Murray's Asylum, Perth, out of 800 cases there had only been five deaths from epilepsy and only three which could be considered to be true cases of status epilepticus. One of the patients was found after death to labour the os was dilated sufficiently to enable two fingers to pass easily through it. She was then examined with the whole hand in the vagina under an anæsthetic; it was found that the tumour had invaded more tissue than was at first realised, so that the cervix could not possibly dilate sufficiently. Enucleation was done the same day under chloroform, the cavity left by the tumour being partly stitched and then packed with iodoform gauze. About seven hours after the operation all uterine pains and contractions ceased, having lasted between 40 and 48 hours, and did not return for 10 days, the os in the meantime closing very quickly, so that a finger could not be introduced. Owing to the packing of the cavity (where the tumours had been) being left off too soon it filled again with blood-clot and the discharge from it became distinctly fœtid; this occasioned renewed packing and washing out. About 12 hours after the baby was born the patient had a severe rigor and her temperature went up to 106·4° F.; this came down gradually in two or three days, the uterus remaining well contracted and free from pain, the lochia remaining of good quantity and colour and free from any taint. She suckled her child and went home to the country with it well within a month of its birth. Dr. Kidd said that he would never undertake such an operation except in a properly equipped hospital, whether private or public, and he would attempt the enucleation before resorting to the induction of labour.—Dr. SMYLY said that tumours of the cervix were very uncommon.

Various specimens were shown by Mr. A. J. HORNE, Dr. R. D. PUREFOY, and others.

---

**LARYNGOLOGICAL SOCIETY OF LONDON.**—A meeting of this society was held on Feb. 7th, Mr. E. Cresswell Baber, the President, being in the chair.—Mr. R. Lake showed a case of Tuberculosis of the Larynx which had been previously under treatment in 1898. The patient had returned three weeks ago with the thyroid cartilage enormously thickened externally and rather hard. Internally there was a conical projection forwards of the right ventricular band. The opinion of the society was invited as to the nature of the thyroid swelling.—Dr. J. Dundas Grant considered it to be a case of tuberculous perichondritis and he advised that the swelling should be opened and explored. —Mr. L. A Lawrence showed a case of Rhinorrhœa of some years' duration in a woman, aged 36 years. There were deflection of the septum to the right and polypoid degeneration of both middle turbinals. The rhinorrhœa was absent only when the patient had a cold. Both local and internal treatment had been adopted for some time without avail.—Several members suggested that in this particular case the proper treatment would be to remove the polypi and possibly the anterior end of the middle turbinals. —Mr. F. G. Harvey showed a case of Lupus Nasi of many years' duration in a man —Dr. H. Lambert Lack showed a case of Partial Membranous Occlusion of the Right Posterior Choana. There existed, also, a perforation of the cartilaginous septum.—The President and others pointed out that the membrane passed upwards from the Eustachian cushion and was posterior to the choana and they considered it to be the result of cicatricial adhesions. The origin of the scarring was attributed by some to congenital syphilis and by others to adenoids.—Dr. Lack also showed a case of marked Chronic Œdema of the Right Arytenoid region in a man, aged 40 years, who had been under anti-syphilitic treatment for three months without benefit. The case was brought forward for diagnosis.—Mr. W. G Spencer excluded malignant disease and concluded that the case was probably syphilitic.—Dr. StClair Thomson suggested that the case might eventually prove to be tuberculous.—Dr. Atwood Thorne showed a case of Syphilitic Ulceration of the Soft Palate occurring during a course of anti-syphilitic treatment The patient was a man, aged 23 years, who contracted syphilis in May, 1901, and had been continuously treated with mercury and iodide of potassium for eight months His general health was very bad. In spite of treatment the uvula and part of the soft palate had been destroyed and ulceration had occurred on the posterior wall of the pharynx —Opinion was divided as to whether it was syphilis alone or a mixed case of syphilis and tubercle. —Dr. Thorne stated that there was distinct evidence of phthisis on physical examination, but no bacilli had been found in the sputum —Dr H. J. Davis showed (1) a case of Tertiary Syphilis of the Pharynx and Larynx in which the voice was produced by means of the ventricular bands; and (2) a case of Laryngeal Tuberculosis with Granulation Tissue between the Cords.—Mr. E. B. Waggett showed a case of Myeloma of the Nose in a woman, aged 30 years. There had been rapidly increasing nasal obstruction since June, 1901, with frequent epistaxis. Rouge's operation was performed and a large tumour was removed. Healing within the nose was rapid and the process was accompanied by so marked a diminution in the size of the cavity that Mr. Waggett asked whether this might be due to recurrence of the growth. It was thought that at present there were no definite signs of recurrence.—Dr. L. H. Pegler showed a case of Abeyance of Nasal Breathing in a female, aged 23 years, in whom the nasal passages were free. The patient also suffered from hysterical aphonia and rhinalgia. The patient's speech though aphonic was "clipped"—a defect known as "rhinolalia clausa." Dr. Pegler thought that both the nasal breathing and resonance were shut off by a spasmodic contraction of the soft palate and with this opinion Dr. Scanes Spicer agreed.—Dr. Pegler also showed a case of Abeyance of Nasal Breathing in which the nasal passages were free and the palate and fauces were hyperæsthetic. In this case also the patient had difficulties in pronouncing the letters *m* and *n*. Dr. Pegler had closed the patient's mouth with his hand, in spite of which she refused to breathe until cyanosis had set in, but finally she respired through the nose. Suspecting palatal spasm, he had fixed the palate by means of a tape passed through the nose and out of the mouth and the patient had been thus enabled to breathe comfortably through the nose with closed mouth —Dr. F. W. Bennett reported that in the case of progressive ulceration of the nose which he had shown at the last meeting he had explored the maxillary antra but had found no pus.—Mr. Hunter F. Tod showed a case of Œdema of the Larynx with thickening of the Palate, Uvula, and Fauces for diagnosis occurring in a boy, aged 10 years. There were no signs of pulmonary phthisis and no evidences of syphilis. Mr. Tod was supported by the opinions of the members present in his belief that the diagnosis lay between tuberculous laryngitis and congenital syphilis —Mr. Waggett showed a case of Ethmoidal Suppuration in a man who complained of excessive pain. The patient had been under treatment for many years, and though the intra-nasal condition was now satisfactory pain persisted. Mr. Waggett suggested that the pain was of neurotic origin, and with this opinion the members agreed.—Dr. Grant showed (1) a case of Subjective Nasal Obstruction which he considered to be due to anæsthesia of the nasal mucous membrane; and (2) some Glass Tubes specially constructed for the Inhalation of Medicinal Powders for the patient's own use.

**NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Feb. 5th, Dr. E. C. Kingdon, the President, being in the chair.—Dr. J. Vincent Shaw (Ilkeston) read notes on a case of Lymphadenoma (?) and showed the patient who was a man, aged 33 years. He had been in good health until two years ago when he developed enlarged glands in the neck which grew rapidly and recurred after removal —The case was discussed by the President, Mr. W. M. Willis, Mr. R. G Hogarth, Dr. W. Hunter, Mr. J. Mackie, and Dr. W. E. Tresidder.—Dr. H. Handford showed a case of Hereditary Diabetes in a boy, aged 12 years, whose grandfather, father, paternal uncle and aunt had suffered from diabetes. Under regulated diet and opium the sugar very rapidly disappeared and the quantity of urine became normal. Two or three baked potatoes were taken daily with benefit, but on repeated occasions one ounce of toasted bread at once caused the reappearance of sugar.—Dr. Handford also read a short paper on the Value of Exercise in Heart Diseases. Exercise, he said, did good rather than harm if the pulse did not remain quickened after two or three hours' rest, if the taking of food was not impaired, or sleep disturbed, and if no undue fatigue remained next day. In many forms of heart disease, especially non-progressive valvular lesions in young persons with full compensation, exercises such as walking, riding, swimming, cricket, and cycling could be practised with moderation to the advantage of the patient. Cases were instanced in which considerable physical exertion had been taken for years with no apparent ill result.—The President, Dr. C. H Cattle, Mr. Hogarth, and D Mutch discussed the subject.—Dr. Cattle related t a woman who, at the age of 47 years, began to paroxysmal cardiac pain (angina pectoris) Considering her age, sex, and a certain far as possible rigidly excluded before the diagnosis of functional cardiac disease is made. It must be borne in mind that the most important signs of organic disease of the heart may be found in other organs. Dilatation and hypertrophy of the heart may follow upon purely functional disease and so change the nature of the case into one of organic disease. On the other hand, functional disturbance may supervene upon organic disease and may thus considerably aggravate the patient's condition.

In the account of the Management of cases of Functional Disease of the Heart the author says that the prophylaxis or avoidance of possible causes of the disease must be attended to. Sanatorium treatment is often to be recommended. Exercise-treatment, gymnastics, and massage are sometimes valuable, but they must not be overdone. The personal influence of the medical attendant is important Digitalis is suitable in a few cases; Nauheim should be avoided in cases presenting excitement. Health resorts more than 1000 metres above the sea and seaside places are not to be recommended.

The second or special part of the work begins with an account of the Functional Disturbances involving the Heart Muscle itself and Acute Dilatation. They are largely due to overstrain and present the symptoms of slight cardiac dilatation. The effects upon the heart of such agents as tobacco, coffee, tea, and the like in excess are next described. In the slighter forms of tobacco intoxication the heart may drop a beat and the intermission produce in the patient a most unpleasant sensation; in the more severe cases attacks may occur resembling angina pectoris. In the section on Functional Derangements of the Heart in the Acute Illnesses a word of caution is uttered as regards the use of antipyretic drugs, and the value of the application of cold, including baths and packs, in stimulating the heart is noted.

In the description of Functional Cardiac Affections occurring in Various Diseases hardly adequate space is given under Anæmia to the differential diagnosis of the functional murmurs, for occasionally considerable difficulty may arise in excluding organic disease of the heart in some cases of anæmia There is an interesting chapter on Organic Disease of the Extracardial Nerves. The urgent symptoms sometimes met with in acute diseases like diphtheria and due to the involvement of the vagus nerves are discussed here. Dr. Hoffmann describes at some length neurasthenia of the heart, the symptoms of which he divides into irritative and paralytic. There may be abnormal sensations in the cardiac region and the pulse may become frequent and even irregular. The diagnosis is said not to be difficult, at any rate when the patient is obviously neurasthenical. In a paragraph on Megrim a case is related in which an attack of tachycardia took the place of an ordinary attack of megrim. In the neuroses following injury the symptoms are said to resemble those of neurasthenia of the heart. The author seems disposed to attach some importance to Maunkopf's symptom in the recognition of a genuine case as against simulation.

In the section dealing with Reflex Disturbances of the Heart the chief attention is naturally given to those which are associated with gastric disease, both functional and organic. There may be abnormal sensations in the cardiac region, also increased rapidity of the heart's action, intermission, and irregularity. The diagnosis must be made with caution in people of advanced years, as, indeed, in all functional derangements of the heart. Adams-Stokes's disease, paroxysmal tachycardia, and Graves's disease are described in the section headed Diseases with a Well-defined Symptom-complex. In the last section the so-called Vascular Neuroses are discussed, such as pulsation of the abdominal aorta, eryphobia (blushing), erythromelalgia, Raynaud's disease, and acroparæsthesia, as well as Erb's angio-sclerotic intermittent dysbasia and intermittent joint effusions.

Dr. Hoffmann has certainly succeeded in giving in a comparatively small compass an interesting and excellent account of a subject to which well-recognised writers on cardiac disease have not always allotted sufficient space. The importance of functional disease of the heart will hardly be questioned, not only on account of its frequency, but also on account of the distress which it causes to those who suffer from it. The author's work constitutes a valuable guide to a knowledge of functional disease of the heart written by one who is obviously deeply read and practically versed in the subject.

---

*A Manual of the Practice of Medicine.* By FREDERICK TAYLOR, M.D, F.R C.P. Lond., Senior Physician to, and Lecturer on Medicine at, Guy's Hospital, Consulting Physician to the Evelina Hospital for Sick Children. London: J. & A. Churchill. 1901. Pp. 1028. Price 16*s*.

THE first edition of this work was published in 1890; the volume now before us is the sixth edition. The success of the text-book, therefore, has been undoubted and we need say but few words as to its general characteristics. The aim of the author has been to offer a short yet complete account of the present state of medical practice which may be useful both to students and to practitioners. In this endeavour Dr. Taylor has been eminently successful. Most attention has been devoted to the description of symptoms, to diagnosis, and to prognosis and treatment. Etiology and pathology are also, of course, considered.

The present edition has been brought fully up to date by a careful revision of the text throughout, by re-writing some of the subjects, by the addition of some subjects not hitherto noticed, and by the insertion of some new illustrations. The subjects which have been most fully revised are malaria, plague, encephalitis, leukæmia, and the examination of the blood. The new matter includes the subjects of myasthenia gravis, paramyoclonus multiplex, acroparæsthesia and acrodactylia, cholecystitis, and polyorromenitis. The last-named term is given to the condition of simultaneous inflammation of two or more of the four great serous membranes, pericardium, pleuræ, and peritoneum—an association to which attention has been especially called by Italian writers. Some of the less common diseases of the skin are also noticed, such as adenoma sebaceum, keratosis, and pityriasis rosea.

Dr. Taylor has followed the arrangement now adopted in most modern text-books by transferring acute rheumatism and gonorrhœal synovitis from the group of diseases of the joints to the section of infectious diseases. This is in accordance with the views now generally held. We cordially endorse the author's remarks as to the loose way in which the term "rheumatic" is employed. Such terms as "rheumatic facial paralysis," "syphilitic rheumatism," and "rheumatic gout" should be excluded from a medical vocabulary, and acute rheumatism or rheumatic fever should be regarded as a definite disease, and as far as possible the term "rheumatic" should be limited to such lesions as can be shown to be directly associated with it.

We have no doubt that this edition of Dr. Taylor's book will attain the same success as that which attended its predecessors.

---

*A Laboratory Course in Bacteriology for the Use of Medical, Agricultural, and Industrial Students.* By FREDERIC P. GORHAM, A.M., Associate Professor of Biology, Brown University, Bacteriologist, Health Department, Providence, R I With 97 Illustrations London and Philadelphia W. B. Saunders and Co. 1901 Pp. 192. Price 5*s*. net.

THE present work, which is described as a laboratory course, is also apparently intended to serve as a guide to the practical details of laboratory work. The author, wisely recognising that it is not the medical student alone who is now interested in bacteriology, has made have a stricture of the colon, which supported the toxæmic theory of insanity. He considered venesection to be of value in some cases. Hyoscine and morphia were not without danger and bromides only controlled the fits.—Dr. R. C. Buist, Dr. C. Kerr, and Professor Stalker discussed the paper.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The fifth meeting of the session was held on Feb. 12th, Dr. Barclay J. Baron being in the chair.—Dr. A. Ogilvy showed a patient with Double Macular Coloboma with persistent hyaloid arteries.—Dr. C. H. Walker spoke on the condition.—Dr. G. Parker showed a patient suffering from Chromidrosis.—Dr. P. W. Williams, Dr. H. E. Stack, and Dr. Ogilvy mentioned similar cases.—Dr. J. Odery Symes showed two brothers suffering from Idiopathic Muscular Atrophy.—Mr. W. H. Harsant showed a specimen of Abscess of the Cerebellum following Otitic Disease.—Mr. J. Paul Bush, C.M.G., Dr. H. Waldo, Dr. F. H. Edgeworth, and Dr. J. L. Firth discussed the specimen.—Mr. Bush showed a Gangrenous Ovary and Tube (due to torsion) that he had successfully removed from the sac of an inguinal hernia.—Mr. W. Roger Williams and Dr. W. C. Swayne spoke on the subject.—Dr. Parker showed a Tumour of the Brain from a patient who had suffered from ear disease.—Mr. Harsant, Dr. Firth, and Dr. Williams commented on the specimen.—Dr. E. W. H. Groves read a paper on Fibroid of the Uterus removed two years after Double Ovariotomy. The specimen was shown.—Dr. Swayne, Mr. Williams, Mr. Bush, and Dr. W. K. Wills remarked on the case.—Dr. B. M. H. Rogers read a paper on a case of Cirrhosis of the Liver in a child which he considered was due to beer-drinking. The specimen was shown.—Dr. T. Fisher, Dr. Stack, Dr. Waldo, Mr. Bush, Mr. Harsant, Dr. Firth, and Mr. J. Handcocke Wathen discussed the paper.

KIDDERMINSTER MEDICAL SOCIETY.—A meeting of this society was held on Feb. 7th, Mr. J. Lionel Stretton, the President, being in the chair.—The President showed: (1) A woman, aged 22 years, whose Elbow-joint he had Excised for Tuberculous Disease five years ago; (2) a girl, aged 22 years, whose Eleventh and Twelfth Ribs approached the Linea Semilunaris on Each Side; (3) a Malignant Kidney removed through the loin from a woman, aged 51 years; (4) the Head of a Femur removed by Amputation at the Hip-joint for Tuberculous Disease, from a lad, aged 17 years; and (5) a Malignant Mass in the Mesentery, with 12 inches of Intestine attached, removed from a man, aged 68 years.—Mr. W. H. Moore showed: (1) A Uterus which he had removed by the Intra-vaginal Method for Malignant Disease, the patient making a good recovery; (2) a Uterus showing Perforation through the Anterior Wall, the result of an attempt that had been made to produce abortion, death following from suppurative peritonitis; and (3) an Extra-uterine Fœtation showing Fœtus and Ruptured Tube.—Dr. O. C. P. Evans showed a girl, aged 15 years, upon whom he had operated for Cancrum Oris by splitting the cheek and scraping away the disease. She made a good recovery and there was likely to be little disfigurement.—Mr. A. C. Oldham read a paper on Rheumatism and a discussion followed.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on Feb. 21st, Dr. Arthur T. Davies, the President, being in the chair.—Mr. T. O. Goodchild showed a man who suffered from three attacks of severe Pain in the Right Iliac Region accompanied by the passing of copious coffee-coloured stools. Relapsing colitis was diagnosed as the cause of the symptoms.—The President showed a specimen of Left Cerebellar Hæmorrhage from a man, aged 63 years, who died in four hours from the initial symptom, headache. The left face and right extremities were paralysed. In a previous paper the President had pointed out that hæmorrhage occurred in the left cerebellar lobe in 33 out of 46 cases that he had collected.—Dr. Alexander Morison read a paper on Cardiac Inadequacy due to a disproportion in muscle bulk to the pumping needs of the organism. The paper was based on two carefully recorded cases of obvious heart failure in (1) an ex-policeman and (2) an ex-soldier. The hearts were found after death to be below the average size and weight and to contain an excess of intermuscular fibrous tissue. Lantern slides were shown to illustrate the heart failure by the sphygmogram and the fibrous overgrowth of the heart.

BIRKENHEAD MEDICAL SOCIETY.—A meeting of this society was held on Feb. 14th, Dr. J. Pinkerton, the President, being in the chair.—Dr. A. C. Ransome read a short note on the question of the Voluntary Notification of Phthisis. He considered that it was the duty of the medical profession to endeavour to prevent disease and not to wait for its occurrence before taking action. As phthisis was an infectious disease he advised that voluntary notification should be adopted. If this were done the houses of poor phthisical patients might be put into a more sanitary condition by the health authorities, and so the conditions under which the patients had to live would be improved. Voluntary notification had been adopted in Liverpool and Manchester with good results.—The President, Mr. F. Vacher, Mr. S. H. N. Harrington, Dr. J. H. Dixon, Dr. W. R. Floyd, and Dr. E. H. Brien spoke in the discussion which followed.—A discussion, adjourned from a previous meeting, on Motor-cars for Medical Men followed.—Mr. Wilkinson, in speaking of petrol cars, advocated them for the ease with which they could be got ready for taking out and also for the fact that they were much cheaper to run than steam cars.—Dr. Brien favoured steam cars, but admitted that they were more expensive in use than petrol cars.

# Reviews and Notices of Books.

*Pathologie und Therapie der Herzneurosen und der Functionellen Kreislaufstörungen.* (*Pathology and Treatment of the Neuroses and Functional Derangements of the Heart.*) Von Dr. AUGUST HOFFMANN in Düsseldorf. Wiesbaden: J. F. Bergmann. 1901. 8vo, pp. 307. Price 7s. 9d.

DR. HOFFMANN divides his subject into a general and a special part. In the former he discusses from a general standpoint the symptomatology of functional cardiac disease, the auscultatory and percussion signs, the relation of functional to organic disease, and the prognosis and treatment, in addition to the physiological and anatomical facts necessary to a proper understanding of the subject. The symptoms include those due to motor and sensory disturbances in the heart. Pain referred to the heart falls under the sensory group and here an interesting description will be found of pseudo-angina pectoris. It is to be distinguished, according to the author, from the genuine angina by its occurrence after psychical excitement but never after bodily exertion. The attack takes place during the waking state and not during sleep unless dreams be the cause of it. In the false form the patient is excited and cries out, and the attack may end in laughing or crying, whereas the mental condition in the true angina is one of silent and often intense anguish. The actual cause of pseudo-angina pectoris may lie in a spasm of the arteries of the heart. Among the motor symptoms alterations in the cardiac rhythm come under consideration. An elaborate and extensive table after Larcena of the causes of tachycardia will be found here. Some have divided bradycardia into a temporary and a permanent form, but this division does not commend itself to the author, since attacks of temporary bradycardia consist in the great majority of cases of merely an aggravation in attacks of a bradycardia permanently present. Something more might have been added to the discussion of bradycardia from the point of view of prognosis. The subject of arhythmia is fully dealt with, including its mode of production. Allorhythmia is to be distinguished from arhythmia, since in the former the departure from the normal rhythm follows in a regular sequence, as in pulsus bigeminus, alternans, and paradoxus.

Dr. Hoffmann quotes M. Huchard's opinion that attacks of arhythmia beginning and ending suddenly are characteristic of arterio-sclerosis. If this is so it would seem very probable that an actual alteration in the myocardium really lies at the bottom of these attacks, and this illustrates the difficulty that may exist in drawing the line between functional and organic disease. This latter subject is dwelt upon by the author in the next section, and he rather lays much stress on the fact that organic disease must

*Hospital Sketches.* By Lucas Galen. London: Grant Richards. 1902. Pp. 153 Price 1s.—These little sketches bear the stamp of truth, as anybody will recognise who has ever worked in a hospital out-patient room. "Lucas Galen" can write English and he has a keen eye for the humorous and, we may add, for the pathetic. Both these qualities are daily to be met with in the out-patient room. The sketches entitled "Placens Uxor" and "Obiter Dictum" will appeal forcibly to many of our readers, but perhaps the gem of the whole collection is "The School Board for London and Medical Certificates." We commend this sketch to the notice of Dr. James Kerr who is about to enter on the arduous duties of medical officer to the London School Board. Dr. Kerr will then see how the Board regards a medical certificate signed by a duly-qualified medical man. Another excellent sketch is "The Conclusion of the Whole Matter." We hope to hear more from "Lucas Galen."

*Brain: a Journal of Neurology. General Index for Volumes I. to XXIII.*—In the spring of 1901 the Council of the Neurological Society decided to publish an index to the first 23 volumes of *Brain* which had been prepared up to the end of the year 1900. A small sub-committee, consisting of the treasurer, the two secretaries, and Dr. R. Percy Smith (the editor), was formed, and the duty of seeing the index through the press devolved on Dr. Percy Smith who was assisted by Dr. W. S. Colman (the senior secretary). The correction of proofs was, we can well understand, an arduous work, as, to make such a book of reference as an index to *Brain* of any value, it is absolutely necessary that every name and title should be verified by reference to the original papers. This has been done throughout the whole of the 23 volumes, representing a large amount of unremitting and unremunerated time and labour for which the whole of the medical profession ought to be really grateful. The index is arranged in two parts—an index of authors and an index of subjects. Included in the index of authors are not only the names of the writers of original papers but also those of authors of books or papers which have been reviewed in *Brain*. In the index of subjects Dr. Percy Smith and Dr. Colman found themselves in the difficulty which every editor of medical and scientific works has found himself in of late: a nomenclature adopted at different periods with regard to the same subject allows that subject to be indexed under two or more headings, while the titles of many of the papers are so complex as to involve insertion under several headings. We congratulate the Neurological Society on placing in the hands of the medical profession a guide book to the storehouse of learning and knowledge contained in the back volumes of *Brain*.

---

## JOURNALS AND MAGAZINES.

*The Library.*—The current number of this quarterly journal contains a very interesting article by Mr. Campbell Dodgson upon "Early Pestblätter." The article is a review of a series of reproductions of early, popular, devotional plague pictures with a descriptive text by Herr W. L Schreiber, published at Strasburg by Messrs. Heitz and Mundel. The chief saints invoked against the plague were the Blessed Virgin, St. Antony, St. Sebastian, and St. Roch The typically medical saints—namely, St Cosmas, St Damian, and St. Pantelemon—do not seem to have been specially invoked against the plague, but in Western Europe these saints were somewhat local celebrities. The cultus of St. Pantelemon (Pantaleone) was, we fancy, exclusively confined to Venice, and St. Cosmas and St. Damian were not much known outside Northern Italy—especially Florence. At first sight it seems difficult to see the connexion between St. Sebastian and the plague. However, as Mr. Dodgson points out, arrows are symbolical of plague, and St. Sebastian was martyred by being shot at with arrows. True, he recovered from the arrow wounds, having been shot at by experts who avoided the vital parts. Appearing more dead than alive before Diocletian, to remonstrate against his tyranny, he was taken out and clubbed to death. Plague, of course, was *plaga*, the blow *par excellence*, and a better quotation as exemplifying the verbal connexion of arrows and "plague" than that from Psalm xci., as quoted by Mr. Dodgson, is afforded by both the LXX. and Vulgate versions of Psalm lxiii., v. 8 (in the Authorised Version, Psalm lxiv., v. 7). The Vulgate runs: "Sagittæ parvulorum factae sunt plagæ eorum." The article is illustrated by a print of St. Roch—"Le très glorieux amy de Dieux, Monseigneur Saint Roch, vray preservateur de la peste," to give him his French title. The plague bubo, perhaps from motives of delicacy or possibly from artistic reasons, is represented at the junction of the lower and middle thirds of the thigh. Of the other articles, "English Book Illustrations of To-day" deals with "Decorative Illustrators." We suppose that "decorative" is used in the sense of "imaginative," but somehow none of the examples reproduced moves us like the work of Sandys. What a magnificent piece of work is the drawing in *Once a Week* to "Yet once more on the organ play," even though the organ pipes are reversed. The article is, however, only the first of a series, and we hope that in the coming numbers some examples will be given of the work of H. J. Ford and J. D. Batten. Wash drawings like those of J. R. Weguelin, who is certainly a decorative illustrator, could hardly be reproduced in *The Library* unless printed on a special paper.

*The Quarterly Journal of Microscopical Science.* Edited by E. Ray Lankester, F.R.S., Adam Sedgwick, F.R.S., W. F. R. Weldon, F.R S., and Sydney J. Hickson, F.R S. With lithographic plates and engravings on wood. London: J. and A. Churchill 1902. New series, No. 179. Vol. xlv., part 3 Pp. 167. Price 10s.—The contents of this part are—1. Dendrocometes Paradoxus. Part 1. Conjugation, by Sydney J. Hickson, D.Sc., F.R S., assisted by J. T. Wadsworth. With two plates. This species of the class acinetaria is obtainable at all times of the year from the commonest of crustaceans, the gammarus pulex, on the gills of which it is constantly to be found. Dr. Hickson states that, in his opinion, in the conjugation of Dendrocometes paradoxus there is a mixing or a shuffling of the molecules of all the essential plasms of the body—namely, of the micro-nucleoplasm, of the mega-nucleoplasm, and of the cytoplasm. 2. On the Oviparous Species of Onychophora, by Arthur Dendy, D.Sc , F.L.S., with four plates which exhibit the appearances presented by the living animals and their anatomica characters. 3 A New and Annectant Type of Chilopod by R J. Pocock, with a plate which depicts the structural features of Craterostigmus Tasmanianus. 4. The Trypanosoma Brucii, the organism found in nagana or tse-tse fly disease. Inoculated mice and rats die rapidly and a flagellated organism is found in great numbers in their blood. It proves fatal to guinea-pigs, rabbits, goats, dogs, and cats, affecting especially the spleen and lymphatic glands as well as being abundant in the blood. It kills the animals at periods varying from five days to 18 weeks. It is a flagellated organism which is apt to fuse with others to form a plasmodium. 5. Notes on Actinotrocha, by K. Ramunni Menon, assistant professor, Presidency College, Madras, with a plate. 6. Review of Mr. Iwaji Ikeda's observations on the Development, Structure, and Metamorphosis of Actinotrocha, by A. J. Masterman, Edinburgh.

---

Wigan Medical Society.—The annual meeting of this society was held on Feb. 11th, when the following were elected officers for the ensuing year:—President: Mr. T. M. Angior. Committee: Mr Angior (president), Mr. W. Latham (vice-president), Mr. W. Mitchell Roocroft, Dr. R. P. White, Mr. C. M. Brady, Dr. John Blair, Dr. Matthew Benson, and Mr. C. R. Graham. Honorary treasurer: Mr E. H. Monks. Honorary secretary: Mr. W. Berry.

the course of such a general character that it may serve as a foundation for future work directed along agricultural and industrial as well as strictly medical lines. The plan of the book resembles that of the "Practical Bacteriology" of Kanthack and Drysdale. Courses of practical bacteriology are usually the outcome of the personal experience of the teacher directed by the special requirements of the institution in which the class is held, and it is not usually easy or satisfactory to graft a course devised for one laboratory on to the teaching of another. A practical laboratory handbook of methods, on the contrary, is of distinct value if those methods are well and accurately described. The present book, though in many respects excellent, suffers from a lack of definiteness of aim. The author is apparently uncertain whether he is writing a laboratory handbook or a course of study devised to give a more general acquaintance with bacteriology. If the latter were the aim the book might be greatly shortened; if the former, the descriptions of methods should be much more detailed and explicit. At present they are condensed to the verge of inaccuracy. Thus in the description of the "hanging drop" no mention is made of any sterilisation of the slide, cover-glass, or water used for suspension of the culture, nor are any precautions suggested for preventing contamination. Such a preparation, it is stated, is used for watching the reproduction of bacteria, but carried out as directed it would lead to strange results. Boni's method for the demonstration of capsules around organisms (p 33) will itself provide an artificial capsule for some organisms. There is in addition a considerable amount of matter which would appear to be more suitably placed in a systematic treatise than in a laboratory book. Of this nature are Chapter IV. on Classification and much of Chapter VII. embodying Chester's work on the systematic description and determination of organisms. It would have added much to the value of the illustrations of this portion of the book if it were distinctly stated which of the specific descriptive terms suggested should be applied to the culture or colony depicted. Chapter IX. deals with the Bacterial Analysis of Water, Milk, Air, and Soil, while the main portion of the rest of the book contains directions for a short study of pathogenic organisms. It is obvious that the ground covered by this book is very extensive, and as it consists of only 192 pages with a large amount of space occupied by illustrations the wonder is that so much accurate instruction and valuable information has been condensed into so small a space. The author rightly insists on the importance of the chemical actions of the organisms. The illustrations are in great part from the atlas of Fraenkel and Pfeiffer and are well reproduced.

---

*The Morphia Habit* By W. OSCAR JENNINGS, M.R.C.S Eng, M D. Paris. London Baillière, Tindall, and Cox. 1901. Pp 210 Price 3s 6*d* net.

IN 1890 Dr Oscar Jennings published the first edition of his book, giving an account of his special treatment of the morphia habit, and in this, the second edition, he revises his previous work in the light of 11 years' additional experience, during which period he has but slightly modified his methods The author has always been a vigorous opponent of the sudden suppression of the drug as recommended by Levenstein and others, and has from the first advocated a rational treatment of the morphia craving upon therapeutic indications That he has found but little to alter in his method during the last decade and that several writers on the same subject in various countries have adopted the treatment first suggested by him, some without acknowledging the source of their inspirations, would seem to afford testimony to its excellence.

The book is written as a guide for patients as well as for practitioners, and perhaps for this reason the author does not give a full account of the symptoms and methods of diagnosis of the morphia habit, or of the dosage of some of the drugs which he employs to counteract the craving and the train of troubles induced by the withdrawal of the drug. The book is, however, well illustrated with notes of cases which supply to a certain extent this information, and the medical reader, though he may favour some method of treatment other than that of the author, cannot fail to profit by the indications as to general treatment which are to be found here. The addition of an index would largely increase the usefulness of the work.

---

## LIBRARY TABLE.

*An Idler's Calendar.* By G. L. APPERSON. London: George Allen 1901. Pp. 213. Price 3s. 6*d.*—This is an elegant little volume of essays most of which have appeared in the columns of the *Globe* newspaper. The articles show wide reading and accurate knowledge of the country. The descriptions of "The English April," of "The Chaffinch," of "Blackberries," of "Autumn Haze," and of "The Apple Month" show accurate powers of observation as well as a pretty imagination.

*The Preservation of the Hair.* By R. W. LEFTWICH, M D. Aberd. Bristol: J. Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co. 1901. Pp. 127. Price 2*s* net —Dr. Leftwich has written a practical little book upon the preservation of the hair. He has made experiments on the elastic qualities of the hair, on the effect of toilet preparations and procedures upon the strength of the hair, and on the value of various forms of "brilliantines," "cleansers," and "bactericides." The book, which is written in simple language with a view of being intelligible to the general reader and in places to the hair-dresser, will correct many widely-spread false impressions among laymen.

*The Congress on Tuberculosis.* By Colonel W. LE POER TRENCH. Second edition. London: Published by the Author. 1901.—Colonel W. Le Poer Trench sends us a pamphlet which consists of reprints of correspondence in the *Times*, which, under the heading of "The Congress on Tuberculosis," resolved itself into a somewhat acrimonious discussion regarding a particular treatment of pulmonary tuberculosis. The fact that since the publication of the pamphlet Colonel Le Poer Trench has again written to the *Times* on the subject prevents us from dealing with the discussion as one that is finally closed, even if, for other reasons, we were not inclined to think that the matter does not concern a medical journal. While we think that Colonel Le Poer Trench is unfortunate in the attitude that he has taken up, we must testify to his obvious and transparent honesty as well as to his courtesy as a letter-writer.

*The Origin of Species.* By CHARLES DARWIN. London: John Murray. 1901. Pp. 432 Price 1*s.*—In view of the fact that one or two editions of Darwin's "Origin of Species" have been prepared to meet the approaching expiration of the copyright of the first edition of that book Mr Murray has placed upon the market a cheap copy of the work. The shilling edition is a popular impression of the corrected copyright edition issued with the approval of the author's executors, and Mr. Murray announces that the edition which has recently lost protection is the imperfect edition which has been reprinted without the authority or consent of Mr. Darwin's representatives. It is an excellent thing that the "Origin of Species" is published in such a form that it can reach the hands of a very large public, and, of course, it is advisable that all Darwin's corrections should be incorporated in the popular edition. We are under the impression, however, that the amount of correction which Darwin found it necessary to make is rather trivial.

THE LANCET.

*LONDON: SATURDAY, MARCH 1, 1902.*

# Publicity for Medical Men in the Lay Press.

Our pages during the past weeks have borne evidence of the very natural indignation which has been aroused by the publication of the names and addresses of sundry medical men (with comments upon their ability) in a book entitled "What's What," a compilation intended to give information about all sorts of things for the benefit of the general reader. This week we publish a letter from yet another injured medical *confrère*. Mr. Harry Quilter, the editor of the work in question, has, we learn, owing to the indignation aroused by his procedure, withdrawn the offending paragraphs with a willingness which we commend. Truth to say, he could do no less, for he sinned deliberately and against the light, as his opening words in Appendix B to the work show. "This paragraph," he writes, "is medically speaking an unforgiveable sin," so that he cannot have been surprised at the resentment aroused. In general, of course, it is not to be expected that the average layman will, or can, understand the rules governing professional etiquette. The average layman looks in books of reference and finds lists more or less accurate of the best butcher or bootmaker or tailor or dressmaker, and he naturally enough thinks that it would be a good thing to be able to choose his "doctor" on the same plan. Mr. Quilter proposed to meet his wants and at the same time to do some persons a good turn by lauding them at large and giving their names and addresses. The state of mind both of Mr. Quilter and of the audience for which he has written with respect to such lists of recommended medical men is largely due to the fact that there is no marketable commodity which the ordinary person is so fond of getting for nothing as medical advice. If he wants special legal advice he knows that he must consult a barrister through a solicitor; if he wants special medical advice he will do anything rather than send for his usual medical attendant and ask his advice with regard to a consultant. In one class of life he will ask any medical man whom he happens to meet out at dinner for advice as to his symptoms or the best authority to consult, in another class of life he will write to a halfpenny evening newspaper. Mr. Quilter apparently decided to catch all these economical and misguided persons as readers of "What's What."

Mr. Quilter's letter which appeared at p. 549 of The Lancet of Feb. 22nd raises two most important points, though one might well have been passed by without comment had it not been that a medical paper has discussed it in an unfortunate manner. It is that the medical men mentioned by Mr. Quilter in his book have directly or indirectly been responsible for the insertion of their names, or have given him a *quid pro quo* for the insertion of their names. We may say at once that the reason why we animadvert upon Mr. Quilter's appendix has nothing whatever to do with such an infamous charge. No one acquainted with the traditions of British literary work or with the traditions of the medical profession could suppose for one instant that the appendix in question was written from a commercial point of view on either side. The editor of the *Medical Times* writing in our columns repudiates having made any insinuation of the sort and objects to this interpretation being put upon his words by Mr. Watson Cheyne and Mr. Quilter. We call his treatment of the situation unfortunate because it was particularly necessary that his words upon such a matter should not be liable to misconstruction and not because we doubt his explanation to be sincere. But it is in regard to the second point—namely, that the publication of medical names is for the public interest—that we differ from Mr. Quilter. The danger in such paragraphs lies in the fact that the public are quite incapable of sifting the chaff from the wheat. Anything which appears in print is taken by the average man for gospel. The medical men mentioned in "What's What" were in the front ranks. But in many instances the medical adviser put forward in a lay paper is very far from being an authority. Occasionally, we regret to say, a medical man himself will write to a lay paper and proclaim, indirectly of course, that he is the first authority upon something or other, and the layman who reads such an effusion is quite incapable of realising that A B, who writes under his own hand, is a pushing ignoramus, and not in the least in the same class as X Y who may be given as an authority, entirely against his will, in a book of reference. It will be a sorry day for the public as well as for medical men if practitioners of medicine ever come to be looked on as standing on the same footing as the purveyors of beef or of drapery, for the appraisement of whose merits no special or technical knowledge is required.

If once it be considered allowable for medical men to be advertised in the lay press the public will see no difference between the real leaders of the profession and the various medical and quasi-medical men recommended in the health and beauty columns of fashion papers, where they appear in company with the Canidias who profess to be able to arrest the ravages of time or to increase the size of the mammary glands. The recommendation of a consultant must be left to someone who knows the patient's constitution and that person is the general practitioner. We do not think that it requires any very subtle intellect to perceive this. It is common for our lay contemporaries to describe medical etiquette as being some impossible rigmarole of rules understood by no one and constructed by medical men to confound their critics. This view is the one usually taken by the lay press. It is generally put forward jocosely, but the joke is getting old, and we look forward to the time when the public will credit the medical profession with obeying a code of unwritten rules that is of the greatest benefit to their patients.

# New Inventions.

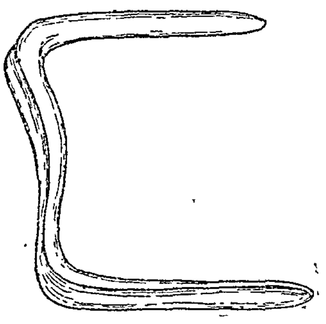
## IMPROVED "RELIANCE" CLINICAL THERMOMETER.

THE accompanying illustration shows a new form of "Reliance" clinical thermometer which has just been brought out by Messrs. Arnold and Sons of West Smithfield, London, E.C. It is of the ordinary round tube pattern, but has a ridge along the whole length of the stem on the reverse side to the index which effectually prevents rolling when placed on a desk or other inclined surface, being in this respect superior to the lens clinical. It is also claimed that it obviates breakage in re-setting the index, as so often occurs in the flat-backed variety which is specially weak owing to its formation and etching, the ridge on the "Reliance" thermometer giving great additional strength to the tube.

## A DUCK-BILL SPECULUM FOR THE FEMALE URETHRA.

CARUNCLE of the female urethra is a very common affection The growths, which are situated almost entirely on the lower floor in or near the meatus, are often somewhat deeply attached and for some distance up the tube. They easily break off and are very liable to recur, especially if the base of attachment is not freely removed The speculum shown in the accompanying illustration has been found very useful in both the examination and removal of these growths. It is made on the principle of a duck bill vaginal speculum; the concave surfaces on the two legs are of different width and are bevelled off at the ends. By hooking up the instrument over the vulva and depressing the upper blade the caruncle can be everted with the lower one and a light reflected on to it For removal with the thermo- or galvano-cautery this arrangement is invaluable I have found it to give a better view than either the ordinary Bryant's vulcanite speculum or the bivalve dilator and is much less painful to the patient than the latter. It has been made for me by Messrs. Wood and Co of York. CHARLES J. WRIGHT.

Leeds.



# ASYLUM REPORTS.

*London County Asylum, Banstead (Report for the year ending March 31st, 1901)*—The average number of patients resident during the year was 2443 The admissions during the year amounted to 547, and of these 463 were first admissions Dr. T. Claye Shaw, then the medical superintendent, states in his report that the number of admissions during the year was the largest since 1891 The mental and bodily condition of the patients admitted was much impaired, and some of the patients (transfers from other asylums) were of a very violent and incurable type. "Drink, privation, worry, and general disease were chiefly responsible for the attacks, and but little was attributable to influenza." In the early part of the year scarlet fever affected five nurses and two female patients, all of whom were treated in the isolation hospital. All made good recoveries. There was no other outbreak of epidemic disease during the year. Six patients escaped, but all were retaken. Two attendants sustained fractures of the leg through being pushed down by patients No other serious casualties occurred in the year. Two male attendants died, one from pneumonia and the other from pulmonary tuberculosis. In May, 1900, 14 nurses passed the examination of the Medico-Psychological Association and obtained certificates. "A practical masseuse has given lessons in massage [to the nurses] I have much hope," adds Dr. Claye Shaw, "from this treatment, especially in cases requiring artificial feeding in conditions of melancholia." The number of patients discharged as recovered during the year was 238, or 9·7 per cent. of the average number resident. The deaths amounted to 247, or 10·1 per cent. as calculated on the same basis. Of the deaths 11 were due to senile decay, 25 to epilepsy, 29 to cardiac disease, 45 to pulmonary tuberculosis, 47 to chronic brain atrophy, 57 to general paralysis, and the rest to other causes. The Commissioners in Lunacy state in their report that the wards and rooms were bright and clean and in very good condition, the appearance of the patients was neat, and the medical case-books and records were well kept.

# Looking Back.

FROM

## THE LANCET, *SUNDAY, FEB.* 29, 1824.

*To the Editor of The Lancet.*

SIR,—Reading in *The Lancet* this week the account of an experiment in transfusion, performed by Dr. BLUNDELL, assisted by myself and others, I beg leave to transmit a few more particulars respecting it. First, it was the blood taken from the carotid artery of one dog, that was injected into another dog, which had been drained till a state of apparent death was produced. Secondly, Dr. BLUNDELL does not recommend the injection of blood into the jugular vein of a woman, but into some vein more remote from the heart, as of the hand or arm for instance. Thirdly, it is not the blood of animals which Dr. BLUNDELL proposes to inject into the human veins, as he tells us in his physiological lectures that he doubts whether the blood of one genus of animals can be safely substituted for that of another, but human blood itself to be taken from the arm of another person by venesection. Fourthly and lastly, Dr BLUNDELL considers it essential to the success of the operation, that by means of a proper instrument the blood be injected into the vein of a patient, as fast as it issues from the vein of the person who emits it, without lodging in the cups of the syringe for more than a few seconds at most. It may not be amiss to add, that the syringe and joints of the instrument, which we employed in this experiment, are made to work under water, so as to preclude the possibility of the entrance of air into the apparatus, as air getting into the veins produces dangerous and even fatal effects

I am, Sir,
Your obedient Servant,
ROBERT JOHN LINTON.

*Guy's Hospital Feb.* 23, 1824.

P S—It is a fortnight since the experiment, and the dog is quite well.

### THE LATE EDWARD GRAINGER, ESQ.

The Friends of this highly talented young man are respectfully informed, that an Animated BUST, the size of Life, has been executed by Mr. HOLLINS, Sculptor of Birmingham, which has met with the decided approbation of his Family, and all who have seen it To meet the wishes of his numerous Pupils and Friends, Mr. H. has been induced to prepare *casts* of it at *Two Guineas each.*

**GIFTS TO HOSPITALS.**—The Leathersellers' Company has sent to the Chelsea Hospital for Women a donation of £10 10s—The Bishop of London, as trustee of the Marriott bequest, has sent a cheque for £1700 to the North-Eastern Hospital for Children, Hackney-road.

be only one head. The present difficulty, he believed, was due to the decision come to by the Council in 1885, and Dr. Russell, in the memorandum to which the Lord Provost referred, predicted the very state of things which had come about. He understood that there was a feeling on the part of some members that there were two distinct departments—the Health Department and the Sanitary Department—but he did not know where any formal statement to this effect was to be found. Throughout the minutes for a series of years they were described as one department, without any acknowledgment that they were two departments. He thought the mistake which had been made was in endeavouring to separate departments which were in their nature inseparable. The medical officer seemed to have acted in accordance with a preconceived idea of what he thought his department ought to be and had not sufficiently kept in mind what its position actually was. Mr. Hugh Alexander said that it seemed to him that the minute had been framed in order to get rid of Dr. Chalmers. If they wished to get rid of him, then let them do it in a straightforward manner, but if they were satisfied that the medical officer ought to be supreme, then why did they not recommend that he should be made supreme? Mr. Fife moved that the minute should be remitted back to the special committee to frame regulations and to define the duties of the medical officer of health and of the sanitary inspector, and their relations to each other, on the basis of the medical officer of health being the supreme and responsible head of all branches of the Public Health Department of the city. On the motion and amendments being put to the meeting Mr. W. F. Anderson's amendment was carried by a large majority. The minute submitted by the special committee was accordingly remitted back to them. We trust that nothing more will be heard of Dr. Chalmers's resignation. The value of his work to the city of Glasgow has been enormous, and the community owes him a heavy debt of gratitude.

## The Midwives Bill.

The Midwives Bill of 1902, which, in accordance with very general anticipation, has now passed its second reading, differs from the Midwives Bill which two years ago reached a similar stage in several of its provisions, while the alterations render it even more open to objection than its predecessor was. The particular alterations, to which we have already drawn attention, although made with little more than the stroke of a pen, are by no means matters of detail: they are of considerable, even of vital, importance to the measure, and transform it into one that in no circumstances ought to become law without very real alteration. The arguments for and against the registration of midwives have been given at length so often in our columns and we have summarised and compared them, substantiated and refuted them, so repeatedly, that it is unnecessary to reconsider the whole question here. Our readers know our views on the matter exactly, and we know theirs to a great extent: they do not all think alike, but a preponderating vote agrees that none of the measures which have yet seen the light is certain to supply the parturient poor with trustworthy attention. What, however, has to be considered now is not the general question but the particular Bill which has now been referred to the Grand Committee on Law. It remains for the medical profession to bring to bear all the influence that it possesses in order that as far as possible the Bill may be made to conform to the medical ideals of public safety. Not only must the latest modifications, which are all for the worse, be removed from the measure, but the many places where the Bill of 1900 failed to satisfy even amiable critics must be looked to.

The main points of difference between the measure of 1902 and that of 1900 are—they will bear repeating though we set them out as recently as in our last issue—(1) the omission of the words penalising the unlicensed practice of midwifery for gain; (2) the laying of the duty of the formation of a Central Midwives Board upon the Lord President of the Council instead of upon the President of the General Medical Council; and (3) the provision that the Central Midwives Board shall frame its rules subject to the approval of the Privy Council, after consultation with the General Medical Council, instead of the rules being framed subject to the approval of the General Medical Council. Among the suggested additions to the Bill of 1900 which should be made when the defaults of the 1902 measure have been attended to are the restriction of the practice of midwives under the Act to normal cases and the compulsory production of evidence of good character, as well as of training and experience, by applicants for midwives' certificates. With regard to the penalising of the practice of midwifery by persons who do not choose to avail themselves of whatever Act may be passed, this appears to us to be of the first importance. The Act will become a dead letter in many districts of the country at once if the unlicensed woman can compete without penalty with the licensed. The insertion of a penal provision constitutes an irresistible inducement to the best of the women who may now be practising as midwives to place themselves under the Act, simply because otherwise they will not be able to practise for gain at all. Undoubtedly the penal clause would also act as a protection to those other women who might be able, unless some provision to the contrary is made, to qualify under the Act as midwives, when their proper style is "Gamps," but this is an inherent fault, as far as we can see, in all Midwives Bills. And a "Gamp" under supervision is to some extent a limited danger, which is one of the things that can always be said in favour of the principle of the registration of midwives. An ignorant woman will naturally prefer to be subject to no restrictions in undertaking any responsibility in connexion with childbirth. She will prefer to retain a position of independence if this can be done without loss of employment. Certainly the penal clause should be re-inserted. The new Bill, as if to emphasise the completeness with which it divests itself of all control over, or interest in, the practice of such women as may not avail themselves of its offer to place them on its contemplated roll of midwives, gives a fresh and simple definition of midwife. A midwife in the new Act is to mean "a woman who is certified under this Act," and nothing more. There is no hint of a definition of the scope of her duties, which is to be left to the Privy Council, acting upon the advice of the General Medical Council. But the law preventing

# The Sanitary Administration of Glasgow.

We regret to learn that difficulties have arisen in connexion with the health department of Glasgow. It is admitted on all hands that as regards the practical carrying out of its work the administration of the department has been most efficient. Our columns have on numerous occasions borne witness to the ability and energy displayed by the medical officer of health of Glasgow and his staff, both in the management of epidemics and in the more prosaic routine duties which have for their object the improvement of the general health of the community. In all crowded populations, and especially in large cities, the conditions of life are now-a-days to a great extent artificial; the enjoyment of life is facilitated, its conveniences are multiplied, and so are the agencies which lower the health of the individual and favour the development of disease This fact, although long known, received little attention from the legislature until some 50 years ago, but an era of diminished urban death-rates was then inaugurated which affords conclusive evidence that medical science practically applied under the direction of the medical profession may be the means of saving thousands of lives every year. In course of time public health departments were formed all over the country, and—curiously enough when the value of the medical work to the community is considered—our columns have only too often recorded the settled tendency and the occasional active endeavours of the majority of these bodies to keep the medical officers in a *sort of tutelage and to limit their authority* as much as possible. Influences of this description have evidently been at work in Glasgow, although the town council in its corporate capacity has succeeded in maintaining an attitude of judicial impartiality, and one of its members has hinted not obscurely that the elastic policy of the Local Government Board for Scotland is in some degree responsible for the unfortunate complications which have arisen. Very important issues are involved, for a crisis has now been reached Matters apparently cannot be suffered to continue on their present footing, and whatever solution may be found the case can hardly fail to have a profound effect on the public health service in Scotland.

The thread of the story, as told in the *Glasgow Herald* of Feb. 19th and 20th, is not difficult to follow. It appears that the medical department and the sanitary department, as at present existing, are distinct from one another, and that the sanitary inspector, who is the head of the sanitary department, is not subject to the control of the medical officer of health The two departments must necessarily have a great many points of contact, with a correspondingly close relationship in the matter of duties, and human nature being as it is the system is evidently such that misunderstandings might be expected. They did not fail to occur, with the result that on July 25th, 1900, the town council appointed a special committee "to inquire into and consider and report as to the cause of certain officials of the Health Department not working in harmony, *and the effect thereof.*" *The report*, which in length does not exceed two columns of The Lancet, was only presented on Feb. 19th, 1902, a special meeting of the town council being held on that day for the purpose of considering it. *The following passages occur in it* :—

> "The special committee, with regret, but without hesitation, have to state that they have had abundant evidence submitted to them showing that want of harmony which the resolution of the corporation implied. ...... The special committee are agreed that distinct and definite regulations under the Public Health (Scotland) Act, 1897, are indispensable, but are of opinion that, before it is possible to frame those regulations, the general relations between the various branches of the department should be settled by the corporation. What those relations should be the committee have very carefully and anxiously considered. They are unanimous in thinking that, in view of the supreme importance of the health of the community, and of the direct bearing thereon of the work of all branches of the Public Health Department, the opinion and advice of the medical officer of health should be paramount, subject to such statutory enactments as may be contained in any Act of Parliament, and to such regulations as the corporation may adopt."

The Lord Provost moved the adoption of the special committee's report in a lengthy speech, commencing with an allusion to the difficulty and delicacy of the task which had been imposed on the committee. He subsequently pointed out that in 1885 Dr. James B Russell, the previous medical officer of health, submitted a memorandum in which he urged the corporation to make the health department include the sanitary department and to place the whole under the medical officer of health, but after heated discussions the corporation declined to accept that advice. The present committee, however, were unanimously of opinion that the medical officer of health should be paramount, and their solution of the difficulty was that a new medical officer of health should be appointed having control over both Dr A K Chalmers, the present medical officer of health, and Mr. Fyfe, the present sanitary inspector Now both these gentlemen are men of high personal character and great professional ability, while they cannot be dismissed because they are statutory officers responsible to the Local Government Board as well as to the corporation. Mr W. F. Anderson reminded the council that Dr. Russell's suggestion that the medical officer ought to be supreme was adopted by the health committee, but rejected by the town council by 25 to 17 votes. In 1897 they got a new Health Act, and the medical profession endeavoured to assert the position which was suggested in 1885 by Dr. Russell, but in both Houses of Parliament their proposals were rejected He quoted the regulations of the Local Government Board to show that the option lay with the town council to decide whether the sanitary inspector should or should not act under the superintendence of the medical officer of health, and he moved as an amendment that the corporation should remit the minute back to the committee with the addition of six members of the Health Committee to draft regulations and to frame by-laws in accordance with the fifteenth section of the Public Health (Scotland) Act, 1897.

On Mr R M Mitchell moving that the corporation should ask Dr Chalmers and Mr. Fyfe to resign their offices, Mr Murray, the city treasurer, said that the real question was whether there were one or two departments. If there were two departments there ought to be two heads, but if there were only *one* there could and it would have been wise for this to have been tested in like manner, as well as the garments which had been near the vaccinated spot. There is, further, the improbability that the plaster which was placed over the whole was so completely secured as to be impervious to dust, and the stocking worn over the leg is also a conceivable source of the bacilli. In these mysterious cases no stone should be left unturned in the attempt to discover the origin of the disease. Nothing can be dismissed as impossible, and no amount of improbability should be allowed to hinder a thorough investigation. Our knowledge of the nature of the virus points out clearly the lines of the inquiry, but we still know little of the channels by which access is gained to receptive surfaces. Moreover, the fact that the exact nature of the cases of tetanus supposed to be idiopathic is still obscure is an additional reason for taking the fullest advantage of every opportunity of learning more of the part which may be played by dust in the production of the disease. The free growth of the organisms in earth is well known, and so also is the great frequency with which the organisms are certainly inoculated where earth obtains access to a wounded surface. But little is known regarding the actual frequency with which the tetanus bacilli exist in the common dust of houses, dust which is inevitably abundant in all the houses of large towns. However strict may be the effort to maintain a high degree of cleanliness, there is probably no house in which sufficient dust does not accumulate in some places to constitute a source of these bacilli; and a thorough examination, however troublesome, should be neglected in no case in which the occurrence of the disease points to the possibility that the search may yield definite results.

## THE ACETYLENE LIGHT IN OMNIBUSES.

IT is not many weeks since the acetylene lamp was made to replace the dirty time-honoured oil lamp in most of the London omnibuses, and very general appreciation was expressed of the great improvement in the interior lighting of the vehicle which is thereby gained. The acetylene lamp undoubtedly gives a powerful white light and the consumption of gas for this brilliant effect is comparatively small. Unfortunately, the acetylene generated from carbide of calcium possesses a very disagreeable odour, suggesting at the same time garlic and the fumes from the moistened tip of a phosphorus match. The least escape of gas is thus instantly detected by the nose, and omnibus passengers have raised strong complaints about it, while the drivers themselves confess that it has sickened many of their number. It is doubtful whether pure acetylene is poisonous, and it is certainly only faintly odorous, but the gas from carbide of calcium is very impure and contains usually a very perceptible proportion of phosphoretted hydrogen and sulphuretted hydrogen to which is due its smell. The former gas is, of course, intensely poisonous, and may easily give rise to symptoms of poisoning, having an exciting action upon the respiratory tissues and an irritating action upon the skin. Sulphuretted hydrogen is also poisonous, but not to the same degree. Acetylene prepared from commercial carbide of calcium may therefore easily prove injurious to health, and there seems to be little doubt that some bad effects are being experienced by the drivers of the acetylene-lighted omnibuses. Health, however, must not be sacrificed for the sake of increased light and something should be done to remove this reproach from the acetylene lamp. The complaints which have been made pretty freely point, of course, to escape of gas, perhaps by draughts, which surely can be remedied, but, failing this, cannot carbide of calcium be purified from sulphur and phosphorus compounds which form highly poisonous gases during the generation of acetylene? "Phossy jaw" amongst omnibus drivers and travellers would be a startling sequel to the installation of acetylene lamps in London omnibuses.

## SMALL-POX IN LONDON.

THE returns of small-pox for the past week show the following figures. On Saturday, Feb. 22nd, there were 44 fresh cases notified and removed; on Sunday, the 23rd, there were 25 fresh cases; on Monday, the 24th, there were 58 fresh cases; on Tuesday, the 25th, there were 63 fresh cases; and on Wednesday, the 26th, there were 44 fresh cases. Within the county of Essex 378 cases have been reported from Jan. 1st to Feb. 22nd. Dr. J. C. Thresh, the medical officer of health of the county, reports under the date of Feb. 24th that there is grave reason to suspect that the disease is being spread by tramps. The medical officer of health of the metropolitan borough of Woolwich, Dr. Sidney Davies, has distributed two leaflets to every house in the borough. The one deals with small-pox and the truth about vaccination, giving plain simple statements which should convince anyone inclined to doubt the efficacy of vaccination, while the other leaflet contains simple hygienic precepts, the precautions to be taken against measles and consumption, and 14 simple rules for "feeding baby." The London County Council has issued a circular to medical practitioners within the county stating that the Council has made an arrangement with 37 medical men who are willing to act as consultants to facilitate the diagnosis of doubtful cases of small-pox. The fees of these gentlemen will be paid by the Council. This is a most important departure, and we believe that our readers will see in the action of the London County Council a real intent to be helpful to them in an arduous time. The difficulty of diagnosing small-pox is great, seeing that the majority of the medical profession in London, fortunately for the London public, have not any familiarity with the disease. It was not an easy task for the London County Council to select the medical men who would be able to assist in the diagnosis of doubtful cases of small-pox, and the list of names has not gone uncriticised. London medical men may, however, be certain that no pains were spared to choose practitioners, to act in an advisory capacity, who had had actual experience of the disease.

## FELLOWS' DINNER OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

A MOST successful dinner of the Fellows of the Royal Medical and Chirurgical Society was held in the Whitehall Rooms on the evening of Feb. 26th, and was attended by some 120 Fellows and their guests. The Vice-President, Dr. C. Theodore Williams, in the absence of the President, Dr. F. W. Pavy, took the chair. The guests of the society were Professor A. W. Rucker, F.R.S. (President of the University of London), Dr. A. Conan Doyle, Sir Walter Sendall, G.C.M.G., Surgeon-General W. Taylor, C.B. (Director-General of the Army Medical Service), Mr. Henry G. Howse (President of the Royal College of Surgeons of England), Sir William Turner, K.C.B., F.R.S. (President of the General Medical Council), Mr. Howard Marsh (President of the Clinical Society of London), Mr. W. Watson Cheyne, C.B., F.R.S. (President of the Pathological Society of London and of the Harveian Society of London), Dr. Peter Horrocks (President of the Obstetrical Society of London), Dr. Urban Pritchard (President of the Otological Society of the United Kingdom), and Mr. J. Y. W. MacAlister (the resident librarian of the society). Dr. Theodore Williams proposed the toast of "Our Patron" His Majesty the King, the third sovereign who had been graciously pleased to be patron of the society. After the toast of other women than a certain class of women from calling themselves "midwives" will not abolish the large existing body of persons using the title. To penalise their gains might stop their vocation, but to legislate about their right to a certain style will have no effect whatever.

The removal of the responsibility for the formation of the Central Midwives Board from the President of the General Medical Council to the Lord President of the Privy Council and the arrangement for the submission of the rules of this board when framed to the Privy Council, leaving the General Medical Council to act in an advisory capacity only, are both retrograde steps. They will, in our opinion, prevent the measure from working smoothly and effectively in the direction desired by its promoters—that is to say, for the good of parturient women of the poorer class. The General Medical Council must know better than the Privy Council whether the rules framed by the Central Midwives Board for the regulation of candidates for the midwives roll, and of their conduct when upon the roll, will conduce to efficiency and harmonious working with the medical profession. Sir **JOHN BATTY TUKE**, who moved the rejection of the Bill at the instance of the General Medical Council, laid no stress on this point. He showed himself to be in accord with the principle of the measure even while he considered its details faulty, and his speech displayed the temperate nature of the objections urged by the medical profession against the Bill. And those objections *are* temperate, although the leaders of the movement for the registration of midwives—those ardent spirits whom the Home Secretary described in his summary of the debate as "desiring much more than anything which was suggested in this Bill"—are wont to term them narrow and bitter. Medical men prove daily all over the country by the lives that they lead and the deeds that they do the reality and depth of their sympathy with the sick poor. General practitioners see more clearly than either obstetric physicians in their wards or philanthropic ladies in their drawing-rooms what the dangers of creating an inferior class of medical practitioners must be to those very women whom the registration of midwives is designed to assist. These dangers Sir **WALTER FOSTER** urged upon the House of Commons on Wednesday afternoon, and we, and many of our correspondents, have pointed them out time after time in the columns of THE LANCET. We trust sincerely that there will be a genuine attempt on the part of legislators to realise them and to provide against them before the Midwives Bill finds its way into the statute book.

# Annotations.

"Ne quid nimis."

## TETANUS AFTER VACCINATION.

THE extremely rare deserves study not less than the extremely common. That which is exceptional not only tests our rules and our inferences, but it often enables us to see facts more clearly and to apply conclusions more precisely. A striking example of the extremely rare is presented by the case of tetanus after revaccination which was recorded in THE LANCET of Feb 22nd, p. 506, by Dr. W. Findlay and Dr. J. W. Findlay. The case is one of great importance, but its importance is far less in regard to vaccination than in regard to tetanus. The danger that vaccination may be a cause of tetanus may be estimated from the fact that it has occurred in this country about once in 5,000,000 cases, and a risk that is represented by one in perhaps 5,000,000 is absolutely negligible. The frequency is somewhat greater, and the risk is correspondingly increased, in tetanogenic countries, but it may be doubted whether even in such countries it is greater than one in a million. It is in regard to the process by which the tetanus organisms may have been introduced into the system, and in regard to the general etiology of tetanus, that the case in question deserves careful thought. The tetanus bacilli cannot have been contained in the lymph employed. Apart from the fact that several other persons were vaccinated from the same tube without ill result, the precautions which are now employed to prevent the presence of extraneous organisms in vaccine lymph should afford perfect certainty on this point. The view of the writers of the paper is that the infection must be associated with the fact that the vaccination was on the leg, and they consider that the trailing skirts of modern days were probably answerable for the collection of the bacilli from the ground and streets and their presence on the skin at the seat of vaccination. The fact that the place inoculated was afterwards protected by a bunion plaster, covered to keep it in position by a strip of ordinary plaster and fixed soon after the vaccination, precludes, it is thought, any subsequent infection, but this view is open to challenge The authors assume that the bacilli must have been previously present in the skin. But it is difficult to dismiss so lightly as they do the inutility of the measures adopted to secure the destruction of organisms The skin was washed with turpentine, then with spirit, and then with a solution of 1 in 40 of carbolic acid. These measures are certainly very different from the "incantation" with which they are compared by the writers of the paper. We cannot think that the process employed would leave the tetanus bacillus within the glands or crypts of the skin, even supposing that they are accustomed to secrete themselves in such a situation. The subsequent access of the bacilli to the inoculated surface, seems much more likely The nearest analogy to tetanus after vaccination, probably, is its occurrence after burns. In these cases it is clearly impossible that the bacilli can have been introduced during the process of burning or that any organisms previously in or on the skin can have survived such application of heat and have been the means of infection. They must have reached the burnt surface afterwards from the air or from materials applied to the burn. Their presence in the air can scarcely be doubted when we remember that they have been found in abundance in the dust of rooms with wooden floors, and in cobwebs applied to arrest the bleeding of wounds. That it is the air from which they gain access to the burnt surfaces is suggested by the fact that tetanus is more frequent after extensive burns than after small burns. In one fatal case, the particulars of which are present to our memory, after a very extensive burn the patient was examined in a certainly dusty casualty room, in the air of which many kinds of organisms must assuredly have been present. In vaccination as now performed the exposure of the surface to the air for some time until the glycerinated lymph is dry is a point to be borne in mind in this connexion, while vaccination on the leg would involve more risk of contamination by dust from the floor than if it had been done on the arm. In any similar case it would at least be wise for dust from the corners of the room in which the vaccination was performed to be collected and an attempt made to ascertain whether it would yield any cultures of the bacilli. Moreover, the bunion plaster placed upon the spot is not likely to have been subjected to any disinfection, and incapacitated him from work. Various hypnotics had been administered without success, and when the patient was admitted into hospital under Dr. Scheib on August 3rd, 1901, his attack had already lasted a fortnight. He was also troubled with vertigo and vomiting. The knee-jerks were exaggerated but there was no Babinski reflex. Ophthalmoscopic examination showed slight papillary stasis but *no* neuritis or retinitis. The pulse was of high tension and the heart-beats were 90 per minute. The arteries were tortuous and slightly atheromatous. The urine contained four grammes of albumin per litre. He was placed on milk diet but this gave no relief or amelioration of symptoms. Lumbar puncture was accordingly performed and 20 cubic centimetres of fluid were slowly drawn off. Microscopic examination showed it to be free from corpuscles. The patient improved within a few hours and on the following day the headache had entirely disappeared. The degree of albuminuria was lessened by milk diet and diuresis was increased. Subsequently he had a second attack of intense cephalalgia like the first, with the addition of a rapidly developed œdema of the face and scalp, probably of angioneurotic character. Lumbar puncture was again performed and 30 cubic centimetres of fluid were withdrawn, after which the cephalalgia subsided. The patient, however, eventually became comatose, with marked constipation, vomiting, and fœtid breath, and died on Sept. 30th while in this state. Dr. Scheib points out that the withdrawal of the cerebrospinal fluid acts in two ways—viz., first by relieving the intracranial pressure, and, secondly, by diminishing the cerebral toxæmia, both of which are factors in the production of such forms of intense cephalalgia as occur in Bright's disease, and in view of the great relief which follows such treatment he recommends its adoption in cases similar to the above.

## SMALL-POX IN THE UNITED STATES.

THE Marine Hospital Service reports from Washington that there were on Feb. 10th last 12,122 cases of small-pox undergoing treatment in the United States. In 1901 at the same period there were but 4359 cases of small-pox throughout the States, and the deaths for the preceding week due to this cause numbered 55. This year during the corresponding week the deaths from small-pox reached the figure of 290. Thus, in the United States as well as in England there are this year conditions prevailing that seem specially to favour the spread of small-pox. Attempts are being made to cope with the disease by imposing quarantine on entire households. For instance, at Philadelphia 85 men have been quarantined at the Samaritan Inn because a case of small-pox was reported to have occurred among them. The police at once established patrols in front and at the rear of this establishment. The inmates were informed that they would be kept prisoners till the quarantine was removed, and that they would be fed at the public expense. This is precisely the same process that the Sultan adopted at Constantinople for all houses or blocks of dwellings in which one or more cases of cholera had occurred. Our Special Sanitary Commissioner, who visited some of these places in 1894, described[1] how the inhabitants regretted the cessation of the cholera epidemic, for they had never before been so well fed. This system, however, is far from meeting with general approval at the hands of the medical profession in the United States. Dr. Shoemaker, chairman of a special committee appointed at Philadelphia to investigate the question, holds that, with proper methods of fumigation and vaccination, quarantine is not necessary and this view is endorsed by three of the five physicians appointed on this committee. They will urge on the city authorities that when the patient has been removed, the other inhabitants of the house have been vaccinated, and the premises have been thoroughly fumigated, it is unnecessary to coop up the dwellers in quarantined houses. Dr. Benjamin Lee, secretary of the State Board of Health, is also an opponent of long quarantine but would compel the people who live in the house where a case had occurred to report themselves at specified times during the period of incubation to a physician appointed for that purpose by the health authorities.

## THE EYESIGHT OF SCHOOL-CHILDREN.

THE medical officer to the Derby School Board, Dr. L. H. Bryson, in his annual report for 1901, deals incidentally with the question of defective vision. He says:—

> I have made 26 visits to the schools, and reported on them separately in my half-yearly reports. Over 700 children were presented for inspection at these visits, two-thirds of whom were cases of defective eyesight. In dealing with these cases, the method adopted is to select the worst, and recommend them to see an oculist. I hope shortly to have a circular printed to send to the parents of those children, which will further impress upon them the necessity of having the eyes specially attended to. On account of their number it is scarcely possible to have the whole of the children with defective eyesight tested and provided with glasses, nor is it necessary, as in many of the cases the defect is slight, and not progressive, and many of the children will not have occasion to use their eyes for fine work after leaving school. In others, again, the effect is due to general malnutrition, or to their not having learned to properly use (accommodate) their eyes, and such cases may be expected to improve.

With reference to the question recently raised in London of having special ophthalmic surgeons to the School Board appointed, Dr. Bryson points out that it takes from 10 to 30 minutes properly to correct defects of vision; that in the case of children refraction cannot be properly estimated without the use of a mydriatic, and that the employment of this without the permission of the parents amounts to a technical assault. Dr. Bryson concludes this portion of his report by stating that instead of treating individual children "general prophylactic precautions must be taken and individual advice may be given, and this is being done in the Derby schools with satisfactory results."

## THE HUNTERIAN SOCIETY.

EPONYMOUS scientific societies or lectures must often seem to the orators and lecturers connected with them to be hard task-masters. It is difficult year by year to find something novel to say about any one man. The great Harvey in founding the Harveian Oration had in his mind that the benefactors of the Royal College of Physicians of London should be commemorated. Unmindful of this mercy, however, the Harveian orator not infrequently rather goes out of his way to commemorate, not so much benefactors in general as Harvey himself. But the Hunterian orator or lecturer has not so much latitude, and we are struck with the skill with which year by year the various improvements and new-old theories of medicine are made to depend from Hunter. Truth, it may be, is a gem with many facets, and Hunter, if anyone ever did, sought the truth. On Feb. 12th Dr. Arthur T. Davies delivered the Hunterian Oration of the Hunterian Society, taking for his subject Organo-therapy. At first sight Hunter and organo-therapy seem as wide apart as the poles. But the difficulty was easily surmounted. Hunter made various observations upon the influence of castration and the periodical changes in the sexual glands of birds and certain mammals. Hence he was led to consider that the testis had an internal secretion. Here at once is the *rationale* of organo-therapy. With equal skill Mr. Reginald Harrison in his Hunterian Lecture, delivered before the Hunterian Society on Feb. 26th, found in Hunter's work and practice lessons for the modern surgeon. The radical cure of hydrocele, the treatment of urinary fistula, and the avoidance of "catheter life" are all even nowadays deeply influenced by John Hunter, and modern surgeons in their treatment of diseases of the urinary apparatus are

---

[1] THE LANCET, Nov. 24th (p. 1239), and Dec. 1st (p. 1301), 8th (p. 1370), and 15th (p. 1442), 1894.

"Her Majesty the Queen, the Prince and Princess of Wales, and the other members of the Royal Family," the Chairman proposed "The Royal Medical and Chirurgical Society." He said that the society had its foundation in 1805 when owing to dissensions in the old Medical Society the new society was formed. Since that date it had steadily advanced in prosperity, meeting at first in the Freemasons' Tavern, afterwards in Berners-street, and in 1890 moving to its present quarters in Hanover-square. The financial condition of the society was most satisfactory. Mr. Alfred Willett (the President Elect) proposed the health of the guests. The toast was responded to by Sir Walter Sendall *and by Dr. Conan Doyle—the latter of whom said that he felt* like a deserter dining with his own regiment and as a full private dining at the officers' mess. The study of medicine was one of the best trainings that a man could go through, and though he was far from wishing to people England with amateur doctors, he thought that the study of physiology, medicine, and surgery for a few years gave a man the truest basis for life and thought He held in the highest esteem *the parish practitioner, who without hope of fame, without* hope of riches, was yet content with duty done. Dr. George Ogilvie, in a humorous speech, showed how the invasion of England by the Scot dated from the Saurian period and had continued to the present day. England had benefited much by the invasion of the Scot, for he had brought with him several excellent things, among which was the game of golf which had introduced an excellent vocabulary *into the English language. The Scot* has also brought with him a song "Auld Lang Syne," which had done more to bring about the federation of the Empire than had Mr Chamberlain. Sir William Turner regretted the absence of the President and expressed his deep sympathy with him in his family affliction. He proposed the health of the chairman of the evening Dr. Theodore Williams replied and the guests separated after a *most enjoyable evening.*

## INTRA-CEREBRAL INJECTION OF ANTITETANIN IN THE HORSE.

IN the February number of the *Journal of Comparative Pathology and Therapeutics* there is a very interesting article by Mr. Sydney Villar, F.R.C.V.S, illustrating the value of the intra-cerebral injection of antitetanin in the treatment of tetanus in veterinary practice. The patient in the first case was a small pony showing visible signs of tetanus when admitted to Mr Villar's infirmary on June 9th. It had walked a distance of three miles and was somewhat distressed on arrival The initial treatment consisted in keeping the patient quiet in a loose box and administering a little belladonna in the drinking water. As trismus became very much more marked, on June 18th intracerebral injections of antitetanin were resorted to. Under antiseptic precautions and cocaine anæsthesia a small circular hole was made through the right parietal bone with an Archimedean drill, and by means of an ordinary hypodermic syringe three cubic centimetres of antitetanin were injected right into the substance of the cerebral hemisphere. The wound was dressed with iodoform and cotton-wool 24 hours later there was a marked abatement of the tetanic symptoms which gradually disappeared within the next 10 days, the pony making an excellent recovery On August 7th there was only a small scar to indicate the seat of operation. The animal was a trick pony belonging to a travelling circus, and it had not forgotten its performance, showing that its mental capacity was not affected in any way, and at no time was there any sign of ill effect from the injection into the brain substance. The second case was that of a hunter which had received a punctured wound in the heel on Nov. 2nd. Tetanus supervened on the 23rd, and by the 26th trismus was very marked, the spasms being very severe. On this date eight cubic centimetres of antitetanin were injected directly into the cranium to a depth of two inches. Immediately after the withdrawal of the needle the horse became very violent and appeared as though it were in an epileptic fit. These symptoms passed off in about five minutes, but it was impossible to dress the wound on the forehead thoroughly. The next day the symptoms had considerably lessened and on Dec. 8th the horse was able to go to walking exercise. As a general rule, if recovery takes place, the horse is at least a month or six weeks before being able to *leave the infirmary. In both the above cases the duration* was scarcely three weeks. These are the first cases which have been recorded in veterinary practice in England. Although a definite opinion can scarcely be formed from two cases, the results are sufficiently encouraging to show that this treatment is worthy of an extended trial.

## THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE: DEPARTURE OF MAJOR RONALD ROSS FOR WEST AFRICA.

MAJOR RONALD ROSS, F.R.S., late I.M.S, sailed from Liverpool on Feb 22nd to join the expedition which is now engaged in sanitary work on the West Coast of Africa under the auspices of the Liverpool School of Tropical Medicine Major Ross has gone out to make an examination of the drainage operations now being carried out in Sierra Leone, and he intends also to prepare statistics as to how the work is progressing. He also purposes to inquire carefully whether any change for the better has taken place in the health of the natives. Among other places he will proceed to the Gambia to examine the drainage there. Sir George Denton, the Governor of the Gambia, and his staff have been engaged for some time in carrying out drainage operations in that colony. Dr. Logan Taylor has been in Sierra Leone for the past eight months and fortunately he has not suffered from malaria—a fact which points to the success of the drainage operations carried out under his directions. Major Ross intends to return to Liverpool at the end of April. Prior to his departure for West Africa he expressed the opinion that if the Government continued the work of drainage and pushed forward other improvements the health of the natives would be considerably improved and the health of the resident Europeans in West Africa would also be safeguarded. Major Ross was seen off by Mr. William Adamson (vice-chairman of the school), by Professor R. W. Boyce of University College, Liverpool, by several students of the school, and by a number of gentlemen who have taken an interest in the work of the expedition.

## INTRACRANIAL PRESSURE AND CEPHALALGIA IN BRIGHT'S DISEASE, WITH REFERENCE TO TREATMENT.

DR. G SCHERB in the *Revue Neurologique* of Jan. 1st last refers to the intense and agonising headache and cerebral toxæmia of Bright's disease and deals with the method of treatment by lumbar puncture which he believes to give almost complete relief. He refers to the recent observations of Dr Marie and Dr. Guillain of Paris who in the case of a patient *suffering from intense cephalalgia of the kind alluded* to above obtained great relief after lumbar puncture, and he cites a second case, confirmatory of the same, published by Legendre. Dr Marie has since then collected five other cases similarly and successfully treated for intense cephalalgia in Bright's disease and Dr. Scherb adds another rare and interesting case illustrating the method and results of treatment The patient was a man, aged 49 years, who suffered from Bright's disease with intense headache and pain in the occipital region of the head which utterly prostrated him

Watson Cheyne, President of the Pathological Society, and Mr. A. D. Fripp. A very enjoyable part of the evening's entertainment was contributed by Dr. A. G. Haydon who gave a violin solo.

### PRIMARY INTESTINAL TUBERCULOSIS IN CHILDREN.

DISCUSSING the question of the transmission of tuberculosis from cattle to the human subject Dr. David Bovaird, jun., of New York, remarks on the scantiness of the evidence to show that tuberculous milk has produced tuberculosis in children. In a paper read before the New York Academy of Medicine which is published in the December number of the *Archives of Pediatrics* he says that he has not been able to find records of more than 22 such cases, the references to which he gives. Moreover, according to most authorities, primary tuberculosis of the intestine is rather unusual. German and French reports unanimously take the view that when tuberculosis attacks children the infection enters by the respiratory tract in almost all cases. Three American reports, based on a total of 369 cases, all from New York city or its environs, give five cases of infection by the intestine—i.e., a fraction over 1 per cent. These reports were published in 1891 by Dr. Northrup, in 1896 by Dr. Holt, and in 1899 by Dr. Bovaird. The English reports present a striking contrast to these figures, for out of a total of 748 cases, 136, or 18 per cent. were cases of primary intestinal infection. Of the articles referred to by Dr. Bovaird as the English reports, one by Dr. G. S. Woodhead appeared in THE LANCET of July 14th, 1888, p. 51; another by Dr. J. W. Carr in THE LANCET of May 12th, 1894, p. 1177; and a third by Dr. L. G. Guthrie in THE LANCET of Feb. 4th, 1899, p. 286.

THE International Dermatological Congress, which was originally meant to take place in 1903 in Berlin, has been postponed till 1904, so that it may not clash with the General International Medical Congress which is to meet in Madrid in 1903. The International Dermatological Congress will meet in September, 1904, under the presidency of Professor E. Lesser. The general secretary of the Congress is Dr. O. Rosenthal, Berlin, to whom all communications should be addressed.

ON Wednesday, March 5th, at 8.30 P.M., at the rooms of the Medical Society of London, Dr. G. V. Poore, the President of the Life Assurance Medical Officers' Association, will shortly review the work of the society and will introduce a discussion on the Influence on Life Assurance of a History of Appendicitis and Insanity.

## LONDON'S PROTECTION AGAINST SMALL-POX.

### A SPECIAL INQUIRY MADE FOR THE LANCET.

ALTHOUGH more than a century has elapsed since Jenner placed in the hands of the medical profession an infallible protection against small-pox the authority in which is vested the control of infectious diseases in London is to-day pressing forward its preparations with all speed to cope with the not unlikely event of a greatly increased prevalence of the malady in the spring of this year. If we have to confess that our effort to eradicate small-pox from our midst has, thanks to the action of the anti-vaccinationists, been a failure we can at least claim with truth that we have not only enormously diminished the extent of its habitual prevalence in the community but also have lengthened the intervals between its epidemic outbursts.

We who live in the twentieth century, perhaps, scarcely realise the large share of deaths claimed by small-pox annually in pre-Jennerian times. In the eighteenth century Hahn asserted that 80 out of every 1000 deaths were caused by variola. De la Condamine held it responsible for 10 per cent. of the deaths in France; while Colin stated that its death toll numbered between 60,000 and 72,000 annually in the same country. In London the average death-rate per 1,000,000 from all causes in 1771–1780 was 50,000; and from small-pox 5020 per 1,000,000. From 1872 to 1890 the annual deaths per 1,000,000 from all causes averaged 21,400; and from small-pox during the same period 178. Since the introduction of vaccination the fraction contributed by small-pox to the total mortality has been reduced from $\frac{1}{10}$th to $\frac{1}{120}$th.

As regards its epidemic prevalence in London we find that during 47 years of the seventeenth century there were 15 outbreaks, and during the whole of the eighteenth century 34 epidemics. This gives a periodicity of one year in every three. The records of other cities show but little improvement on this state of affairs. Thus in Copenhagen in the latter half of the eighteenth century there were epidemics once in four years, in Geneva once in five years, in Edinburgh once in three years, and in Boston, U.S.A., once every fourth year. Coming to our own times we find that since 1870 there have occurred in London epidemics in 1871–1872, 1877–1878, 1881, 1884–1885, and 1893. So that during the last 32 years we have passed through five epidemics and are now on the threshold of a sixth. This is a gain of which we cannot boast much.

During the first five months of 1901 small-pox may be said to have been practically absent from London. From March up to May 29th not a single case occurred. On the last-mentioned day a patient was admitted from Islington, on June 10th one from Whitechapel, on June 29th one from Hackney, and on June 28th and 29th one on each day from Wandsworth. During July and up to August 21st single cases were notified from various parts of London. From this date onwards the disease obtained a hold on St. Pancras and Marylebone, and very soon afterwards cases were admitted from every one of the 31 Poor-law parishes and unions comprising the Metropolitan Asylum District.

In taking its rise during the late summer and spreading over London through the autumn and winter the present epidemic is considered to have pursued a most unusual course. In an ordinary way small-pox is most prevalent during the first seven months of the year, and especially so in the spring. Thus, during 1893 the bulk of the patients were admitted between January and the end of July. During that epidemic the largest number of patients under treatment on any one day occurred on May 15th when they reached 571; and the largest number—viz., 536—were also admitted to the hospitals during the same month. From the report of Dr. Brooke, who was stationed at the wharves in 1893, we gather that the number of admissions from March to July were for each month respectively: March, 241; April, 413; May, 511; June, 312; and July, 200.

Dr. Long, the second medical officer of the river ambulance service, who compiled the history of the epidemic of 1893, placed its start at the end of October, 1892. From that date it gradually increased until, by the end of January, 1893, there were foci of infection everywhere east of a line running north and south through Euston Station. Not long after this the disease had cropped up everywhere in the metropolis. As regards the seasonal prevalence a very similar course was followed in the other epidemics since 1871. If we may argue, therefore, from our experience in former years we must look forward, not to a decline, but to a serious increase of small-pox in the near future.

As small-pox is not only permanently established in London but is liable to attack the city in epidemic form it is necessary that the Metropolitan Asylums Board should make provision for the reception of patients, not only when the disease prevails to an average extent, but also that its resources should be sufficiently elastic to enable it to cope successfully with the most formidable of epidemics. What the exact amount of accommodation ought to be which the Board should have at its disposal is, however, by no means an easy question to answer, as the fluctuations in the amount of small-pox prevailing are enormous. Thus in 1884 and 1885 there were over 6000 cases under treatment annually; whereas in 1889 and 1898 only five persons suffered from this disease during each of these years. Nevertheless, to be of real use the Board must keep an isolation hospital in constant readiness, whether there are patients to occupy it or not. It is calculated that this provision will cost London £10,000 per annum—apparently a considerable outlay, but small when we remember that the but carrying out the principles laid down by him. In forthcoming numbers we hope to publish both the oration and the lecture referred to.

## THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Mauritius received at the Colonial Office on Feb 21st states that for the week ending Feb. 20th there were 13 cases of bubonic plague, of which 11 proved fatal. As regards Egypt during the week ending Feb. 16th 8 cases and 8 deaths from plague have been reported from all Egypt. 6 cases and 7 deaths were reported from Tantah and 2 cases and 1 death from Kom-el-Nur, a village near Mit-Ghamr. All these cases and deaths occurred among the native population. 5 of the deaths at Tantah and the one at Kom-el-Nur occurred out of Hospital.

## THE VACCINATION LEAGUE.

THOSE who are desirous of obtaining free literature dealing with the advantages of vaccination, or of organising popular illustrated lectures on the subject in their respective districts, should apply to the offices of the Vaccination League, 110, Strand, W.C Among the influential names recently added to the long list of vice-presidents of the Vaccination League are those of the Bishop of London, Archdeacon Sinclair, and Lord Newton. It will be remembered that Lord Newton recently introduced a Bill into the House of Lords on the subject of Vaccination

## ST. BARTHOLOMEW'S HOSPITAL AND CHRIST'S HOSPITAL.

LORD BALFOUR of BURLEIGH, the appointed arbitrator in the dispute between the authorities of St. Bartholomew's Hospital and Christ's Hospital, gave his decision on Feb 25th St Bartholomew's Hospital is given an area of 67,680 square feet at a cost of £238,781. Our readers will remember that in our issue of August 11th, 1900, p. 408, we published a map of the area in dispute The area now awarded is slightly in excess of that marked in the map St. Bartholomew's Hospital originally offered £117,000 for about 1½ acres. It now has to pay £238,781 for an area of a little more than 1½ acres, being an excess of £121,781.

## TYPHOID FEVER AT PHILADELPHIA.

FOLLOWING upon the winter rains, the disturbance of mud, and deposits by the torrential flow in the water-courses, another epidemic of typhoid fever has broken out in Philadelphia; and in the havoc achieved this disease is running a neck-to-neck race with diphtheria and small-pox. The city Bureau of Health reports that during January 334 cases of diphtheria, 433 cases of small-pox, and 432 cases of typhoid fever were notified. But during the week ending Feb. 1st there were 201 cases of typhoid fever and this already outstrips last year's record. The worst weeks in 1901 were those ending on May 25th with 142 cases and on August 31st with 152 cases. The water-supply is considered to be the cause of the present as it was of the previous epidemic, and 600 men are now employed, working day and night, in the construction of new filtering beds which are to yield 6,000,000 gallons every 24 hours But when the beds are completed the water must remain there for some time so as to press down the filtering materials and to impart sufficient compactness to ensure perfect filtration. Even when this is achieved the water can only be delivered at the low levels Another filtering bed of the same capacity is in course of construction at a higher level, and it will be necessary to pump the water up to this point. These more extensive works will not be completed till the month of May at the earliest, so that there is still ample time for the epidemic to spread. Considering the emphatic warning given by the numerous epidemics of typhoid fever which have occurred at Philadelphia it is difficult to explain why so important a city has been left for so long without a proper and safe water-supply.

## BRITISH CHILD-STUDY ASSOCIATION.

THE report of the committee of the London branch of the British Child-Study Association for the year 1901, of which Dr. Fletcher Beach is president, has just been issued. It states that 115 new members joined the branch during the past year, bringing the total of the roll to 216. The object of this association is to gather and to spread information about the life and training of children by (1) collecting records of careful observations of individual children; (2) collecting personal reminiscences of childhood; and (3) tabulating the results of studies of papers written by children These collections and the results so obtained are carefully studied and as far as possible conclusions are drawn from them. Various circles for study are also formed in connexion with the society, and lectures are delivered once a month in the Ruskin Room of the Sesame Club, Dover street, Piccadilly, W. The subscription is 2s 6d. a year, which entitles the member to a copy of the *Paidologist* the official organ. We regret to note that the subscriptions last year did not cover the expenses An association which does such good work ought not to be in need of funds, and we feel sure that if the association were better known to the public adequate support would be forthcoming.

## THE ANNUAL DINNER OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE West London Medico-Chirurgical Society held its annual dinner on Feb 19th at Frascati's Restaurant, Oxford-street, W. The President of the society, Mr. A Cooper, occupied the chair. The Director-General of the Army Medical Department, Surgeon-General W. Taylor, C B., in acknowledging the toast of "The Imperial Forces," proposed by Mr. C B. Keetley, said that he did not think that his was the only department that had shown shortcomings, and he was sure that the officers and men of the Royal Army Medical Corps could hold up their heads equally well with the members of any other department of the army. The officers of his department were members of the medical profession and they felt that the sympathy which they received from its civil members was their greatest reward. Dr. W. H. Allchin (President of the Medical Society of London), who replied to the toast of "The Kindred Societies" given by Mr. Swinford Edwards, referred to the relationship that existed between the Medical Society of London and the West London Medico-Chirurgical Society in that both were founded to embrace all branches of the profession. Mr. L. A Bidwell proposed "The Guests" which was replied to by Sir J. Crichton Browne who discoursed upon the appalling flood of medical literature Daylight and midnight oil, he said, could not suffice to carry a man through even a small portion of the works published, and he was compelled, like a swallow, to flit here and there and to pick up a miscellaneous cropful of undigested medical and surgical information. The toast of "The President" was proposed by Dr James B. Ball and that of "The Officers of the Society" by Dr. F. J. McCann The latter was acknowledged by Mr. H Percy Dunn, the editor of the journal of the society, and by Dr. L C. T Dobson, the senior secretary, who said that at their next meeting the number of the members would be over 600. Among the guests were Sir William Church, President of the Royal College of Physicians of London; Mr. H. G. Howse, President of the Royal College of Surgeons of England; Mr. W.

put to bed in one of the wards. A mild case is in a few days' time again put on board a steamer and carried to the opposite shore, whence he is conveyed by ambulance to the Upper Gore Farm Hospital. Bad cases are detained at the ships and when convalescent are drafted on to Gore Farm. When the permanent hospital at Joyce Green is finished and the ships are no longer in use the patient on arriving at the pier, Long Reach, will be lifted on his stretcher in a tramcar, and conveyed either to Joyce Green or, if there be no room there, to the Orchard Hospital, with which it is connected by a branch line. A patient will thus be carried on a stretcher from his own home in London and deposited in the Board's hospital at Dartford without being disturbed from the recumbent posture.

Every visitor to a patient—visitors being allowed only in the case of a patient who is dangerously ill—is pressed to be vaccinated, but acceptance of vaccination is not insisted on as a *sine quâ non* before seeing the sufferer. The precaution, however, is taken of forwarding the names and addresses of all visitors, whether vaccinated or not, to the medical officer of health in whose district they live.

The wealth of clinical material in the Board's small-pox hospitals has up to the present been practically wasted as a means of instruction. but arrangements are now being made for teaching medical students and qualified practitioners the diagnosis and treatment of variola by demonstration of typical cases. Every attendant at these classes must satisfy the medical superintendent that he has been efficiently revaccinated fairly recently or is protected otherwise against small-pox, and must observe the rules regarding clothing and disinfection while in the hospital.

We have endeavoured in this article, after sketching the history and growth of the present epidemic, to show what resources the Board had at its command to cope with the outbreak at its start and to trace the steps by which the managers of the Hospital Committee have strenuously endeavoured to grapple with the storm that threatened to overwhelm them. From a personal inspection of the Board's hospitals we can testify that the managers have the epidemic well in hand and that there was no overcrowding at the hospitals. We feel sanguine that the Metropolitan Asylums Board will accomplish the ideal it has set itself—viz., to extend its protection to every patient who seeks its help.

---

# THE METROPOLITAN WATER-SUPPLY.

## THE EAST LONDON WATERWORKS COMPANY: SOME QUESTIONS FOR THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD.

IT may be useful at the present time to recall certain facts in regard to the history and present condition of this company. From these it will be seen that—

1. The sources of supply of the company are inadequate.

2. The arrangements made by the company for the purification of the water which it abstracts from the Thames are unsatisfactory.

1. In regard to the first point it may be well to give a brief quotation from the last published annual report of the Water Examiner appointed by the Local Government Board.[1] It may not be out of place here to point out that the reports of this gentleman usually place the proceedings of the companies in the most favourable light possible. To cite one example only, from the last annual report, given in regard to the East London Company (p. 245), it is said: "The waste of water in the district is very considerable and there is great difficulty in controlling it." This statement evidently came from officials of the company, whose ideas of waste do not always correspond with those of water consumers. The fact that the East London Waterworks Company has failed in successive years to supply its customers may, however, best be given in the words of the official record: "In 1895 and 1896 and again in 1898 and 1899 ...... the East London Company owing to the inadequacy of their storage reservoirs were unable to deliver from their own sources of supply sufficient water to meet the requirements of their district. During the summer of 1895 an interruption in the constant supply took place which culminated on July 15th in the shutting off of the water-supply of the whole district, containing a population of 1,200,000, during 21 hours out of every 24." A constant service was not fully restored until Oct. 8th. In the year 1896, on July 17th, the company reverted to an intermittent system of supply, which was continued until Sept. 19th. On August 22nd the supply given again became intermittent and was reduced to two periods of three hours each daily. This state of things continued until Sept. 3rd, when the daily supply was further reduced to two periods of two hours each. Constant service was not given throughout the whole district until Dec. 14th. The condition of things in the East-end would have been more distressing than it actually was had it not been that water was obtained from some of the other metropolitan companies. The New River Company did not take its full draught from the Lee and the water was allowed to flow down to the East London Waterworks Company's intake. The Southwark and Vauxhall Company pumped water through a main which was quickly laid through the Tower Subway for the supply of the low-lying district just north of the Thames. The Kent Company sent some water through the Blackwall Tunnel for the supply of the Limehouse district. From July to November inclusive the East London Waterworks Company received no less than 1,158,010,000 gallons of water from sources other than its own; "but it may nevertheless be assumed," says the Water Examiner, "that during this period the supply was short of the demand to the extent of from 700 to 750 million gallons." During the summer of 1899 the sources of the East London Waterworks Company again proved inadequate, and from July to November inclusive no less than 1,898,846,000 gallons were received from other companies. Since this date improvements have been made, but the sources of supply of the company are still insufficient, as a study of the periodical reports of the Water Examiner clearly shows. The annual report will not presumably be published for some months, and the table which is given here has been compiled from the monthly reports.

*Table showing the Sources of the Water Supplied by the East London Waterworks Company and the Average Daily Amount derived during each Month of the Year 1901. (Compiled from the Tables given in the Monthly Reports of the Water Examiner to the Local Government Board.)*

| Month. | Sources. | | | | | Total. |
|---|---|---|---|---|---|---|
| | Lea and Storage. | Thames. | Hanworth Springs. | Wells. | Wells "per New River Company." | |
| Jan. | 23,559,000 | 7,731,000 | 1,543,000 | 6,688,000 | — | 39,521,000 |
| Feb. | 23,260 000 | 8,469,000 | 1,390,000 | 5,837,000 | — | 38,956,000 |
| March | 27,736,000 | 5,282,000 | 1,265,000 | 3,720,000 | — | 38,003,000 |
| April | 28,561,000 | 5,103,000 | 1,345,000 | 3,773,000 | — | 38,782,000 |
| May | 27,939,000 | 6,489,000 | 1,512,000 | 5,531,000 | — | 41,521,000 |
| June | 21,277,000 | 11,968,000 | 1,521,000 | 10,367,000 | — | 45,133,000 |
| July | 11,663,000 | 19,126,000 | 1,573,000 | 12,148,000 | 2,636,000 | 47,146,000 |
| August | 10,724,733 | 19,107,000 | 1,519,000 | 10,642,000 | 3,745,267 | 45,738,000 |
| Sept. | 9,928,264 | 19,317,000 | 1,544,000 | 11,799,000 | 1,740,736 | 44,329,000 |
| Oct. | 12,393,000 | 16 058,000 | 1,595,000 | 12,000,000 | — | 42,051,000 |
| Nov | 17,323,000 | 8 895,000 | 1,599,000 | 11,356,000 | — | 39,173,000 |
| Dec. | 19,829,348 | 7 151,000 | 1,524,000 | 8,207,000 | 443,652 | 37,155,000 |

2. The second point to which we wish to direct attention is that the arrangements at the Thames station of the company are inadequate to insure the purification of the water treated. The Thames water is pumped from Sunbury to Hanworth. The station at Hanworth possesses a "subsiding and storage reservoir" capable of holding 5,000,000 gallons of water. From this reservoir the water passes to the filter beds, of which there are six, which have a total area of five acres. It therefore practically happens that Thames flood water is introduced to the filter beds without undergoing the preliminary purification caused by subsidence.

Is the President of the Local Government Board aware that the Balfour Commission held that the water which flows down to the intakes of the companies "must be subjected to certain important processes before it can be brought into a suitable condition for delivery and consumption," and that epidemic in 1884 cost about a quarter of a million of money from the loss of lives and dislocation of trade.

---

[1] Thirtieth Annual Report of the Local Government Board, 1900–1901. London, 1901.

In July, 1896, the Metropolitan Asylums Board submitted to the Local Government Board plans for the erection of a permanent small-pox hospital at Joyce Green for a total number of 940 beds—a number which the Board considered a not unreasonable provision for future contingencies. The Local Government Board, however, at that date declined to consider the proposal and held that the erection of pavilions should be limited to the accommodation of 400 patients only, any extra room to be provided for by the erection of temporary buildings in case of an epidemic. With this partial sanction of its scheme the Metropolitan Asylums Board was forced to rest content and instructed its architect to press on at once with the erection of 10 blocks for the reception of 436 beds, and with buildings for the accommodation of officers, nurses, and servants, kitchen and laundry. At the same time provision for heating, lighting, water, and drainage was provided for on a scale suitable for 940 beds. In November, 1901, in the face of a growing epidemic, the sanction of the Local Government Board was obtained for the erection of the remaining 12 blocks to hold 504 patients

The Joyce Green Hospital stands upon an inclosure of 100 acres of ground and consists of 22 pavilions built on each side of the arms of a wide V. There will be four isolation blocks capable of holding 60 patients whom it may be necessary to remove from the general wards for one reason or another. The wards are of an oblong shape and will contain 20 beds each with an adjoining room for two more patients who may be delirious or too seriously ill to be amongst the rest. There is a nurse's room at the end of each ward from which she is able to command a view of the whole through glass windows. The lavatories and a bathroom are separated from the ward by a lobby with cross ventilation. There are other blocks for the medical staff and employés and a house for the nurses in which each nurse and assistant nurse will have her own room. The hospital is lighted by gas and warmed by steam. It is provided with its own destructor furnace and a Lyons disinfecting chamber. The hospital will be supplied with water from the company's mains, but is provided with a reserve tank capable of storing 50,000 gallons of water. The total cost of the building will be £299,798, or about £320 per bed. It is probable that the first section of 10 blocks will be ready to receive patients in six months time. It is therefore doubtful whether this hospital will be of much use during the present epidemic.

We have seen that in 1896 the Metropolitan Asylums Board considered that the minimum permanent provision which it ought to have at its disposal for small pox should be 940 beds. Through no fault of its own the execution of this scheme was delayed; and at the outbreak of the present epidemic in the autumn of last year the Board found itself face to face with the unpleasant fact that it had only 250 available beds for small-pox at the hospital ships. The Royal Commission in 1882 gave it as its opinion that about 2700 beds should be provided for small-pox in London, the population of which then numbered about 3,900,000. Obviously, for the present epidemic spreading amongst a population of 4,500,000, at least that number would have to be got ready. The Board's only other available hospital, the Upper Gore Farm, was at that time being used for fever patients In the early autumn this hospital was cleared of those patients and disinfected; and on Oct. 30th small-pox patients were admitted to it On Nov. 2nd the Board ordered the erection of additional staff and isolation quarters at Gore Farm, and thereby freed the rest of the hospital for small-pox cases and secured a total of 1000 beds, making in all 1250 beds available

As small-pox showed no signs of decreasing the Board on Nov. 2nd determined on the erection of a temporary hospital at Long Reach, capable of holding 300 patients The Long Reach Hospital is built close to the banks of the river and consists of 12 blocks with additional pavilions for administrative and isolation purposes Each of the 12 blocks contains 24 beds and is built with a double wooden floor with felt between The walls are of weatherboarding lined with felt and finished on the inside with matchboard The roof is also lined with felt and covered with a thick waterproof cloth The blocks stand on footings of brick resting on a solid bed of concrete. Heating is by steam-pipes and the lighting is by gas. Close to the floor and near the steam-pipes are inlet ventilators, the outlet ventilators being the windows and shafts in the roof.

In the early part of January, 1902, the Board further ordered the erection of the Orchard Hospital for 800 beds on the Joyce Green estate. This hospital will be a temporary wooden structure built in pavilions arranged in three parallel lines, very much after the pattern of the hospital at Long Reach. The Shone system will be adopted in the disposal of the sewage of this hospital.

Finally, the Lower Gore Farm Hospital with 190 beds will also be pressed into the service of the small-pox hospitals, and orders for its extension have already been given, which when completed will bring the Board's total available small-pox provision to 3200 beds. The beds will be distributed as follows: hospital ships, 250; Long Reach, 300; Orchard, 800; Upper Gore Farm, 1000; and Lower Gore Farm, 850.

The present epidemic will probably be the last occasion on which the ships will be used as small-pox hospitals. We may therefore say a few words here as to their history and structure and as to the reasons that have induced the Board to discontinue their use. The hospital ships consist of three vessels, the *Atlas* and *Endymion*, which were purchased in 1881, and the *Castalia*, which was purchased in 1884. The two former were originally built for the navy, and the latter was a twin ship intended for service between Calais and Dover, for which she proved unsuitable. The *Atlas* and *Castalia* are used for patients and the *Endymion* for administrative purposes only. The three ships are connected together and moored in the Thames off Long Reach. Upon the upper deck of the *Castalia* five huts have been erected obliquely across the long axis of the vessel. These huts form the wards of the upper hospital, the lower hospital consisting of one single ward which runs the whole width of the vessel. There is one isolation room on the lower deck and two on the upper deck. At each end are lavatories, bath-rooms, reception rooms, &c. A laundry and other administrative buildings have been erected on shore close to the ships. Time and weather have told heavily on the ships, and they now stand greatly in need of considerable repairs. The extent of the latter cannot be gauged until the vessels have been dry-docked and overhauled thoroughly, but it is certain that if efficiently carried out several thousand pounds would have to be expended. The Board are of opinion, however, that for a small outlay the ships can be patched up sufficiently to enable them to continue in use until the permanent hospital at Joyce Green is ready Moreover, ships are an excessively costly form of hospital to administer, their upkeep, exclusive of patients' maintenance, entailing an annual expenditure of £9500. We might mention, amongst other disadvantages, the risks of delirious patients jumping overboard, the possibility of collision with passing vessels, and the dangers of fire. All these accidents have happened during the period the ships have been in use Again, quite recently they have been accused of disseminating small-pox at Purfleet and Orsett, and there seem to be good reasons in support of this view, as appeared from the report of Dr. J. C. Thresh which was published in THE LANCET of Feb. 22nd, p. 495

Not the least serious and important of the questions relating to small-pox is that of the disposal of the dead The Board have decided that this shall be by burial within the grounds of the Joyce Green Hospital. For this purpose a site three acres in extent has been fenced off at the south-east corner of the estate and laid out as a cemetery. At the present time it is impossible to see what other course the Board could have adopted than earth-burial. Possibly at some future time, when public opinion has been educated up to it and relatives' feelings will be less shocked by the proposal, a scheme may be formulated for the disposal by cremation of the bodies of all patients dying not only from small-pox but from other infectious diseases.

We may now briefly describe the steps whereby a patient suffering from small-pox is removed from his home and obtains admission to the Board's hospital. On receiving notice of the occurrence of a case of small-pox in a house within the Metropolitan Asylums district an ambulance with a nurse is despatched to the address. The patient, wrapped in blankets, is placed lying down at full length in the ambulance and is driven to the South Wharf, Rotherhithe. Here he is inspected by Mr. W. McC. Wanklyn, an expert in the diagnosis of small-pox. If the patient is found not to be suffering from small-pox he is sent back. Should the case be doubtful he is detained at the shelter until such time as the diagnosis becomes clear If the case be one of undoubted variola he is carried on his stretcher and placed on board a river ambulance steamer and conveyed down the Thames to the ships at Long Reach. Here he is in Newcastle, 32·7 in Plymouth, and 36·2 in Merthyr Tydfil. The 6959 deaths in these towns last week included 581 which were referred to the principal zymotic diseases, against 584 and 525 in the two preceding weeks; of these 581 deaths 145 resulted from measles, 139 from whooping-cough, 99 from diphtheria, 69 from small-pox, 49 from scarlet fever, 44 from "fever" (principally enteric), and 36 from diarrhœa. No death from any of these diseases was registered last week in Hornsey, Hastings, Aston Manor, Newport (Mon.), or Swansea; while the highest zymotic death-rates were recorded in Brighton, Hanley, Burton-on-Trent, Bootle, Burnley, Rotherham, Stockton-on-Tees, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Stockport, Burnley, Preston, and Merthyr Tydfil; from scarlet fever in Tottenham, South Shields, and Newcastle; from diphtheria in Hanley, Burton-on-Trent, King's Norton, and Stockton-on-Tees; from whooping-cough in Brighton, Bournemouth, Birmingham, Coventry, Bootle, and Gateshead; and from diarrhœa in St Helens. The mortality from "fever" showed no marked excess in any of the large towns. 69 deaths from small-pox were registered last week and of these 64 belonged to London, two to Tottenham, two to West Ham, and one to East Ham. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 1102 and 1185 on the two preceding Saturdays, had further risen to 1321 at the end of last week; 502 new cases were admitted during the week, against 499, 287, and 390 in the three preceding weeks. There were 2406 scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday, Feb. 22nd, against numbers decreasing from 3137 to 2455 on the eight preceding Saturdays; 219 new cases were admitted during the week, against 226, 277, and 260 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 375, 486, and 681 in the three preceding weeks, further increased last week to 885, and were 363 above the corrected average number. Influenza was stated to be the primary cause of 107 deaths in London last week, against 26, 40, and 51 in the three preceding weeks. The causes of 101, or 1·4 per cent., of the deaths in the 76 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, and 35 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, St. Helens, Warrington, Halifax, South Shields, and Newport (Mon.).

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·8, 23·9, and 23·6 per 1000 in the three preceding weeks, rose again to 25·3 per 1000 during the week ending Feb. 22nd, and exceeded by 0·9 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 22·1 in Edinburgh and 23·7 in Paisley to 28·4 in Leith and 37·1 in Greenock. The 817 deaths in these towns included 22 which were referred to diarrhœa, 20 to whooping-cough, 17 to measles, seven to small-pox, six to diphtheria, six to "fever," and three to scarlet fever. In all 81 deaths resulted from these principal zymotic diseases last week, against 83 and 66 in the two preceding weeks. These 81 deaths were equal to an annual rate of 2·5 per 1000, which was 0·5 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 23 and 16 in the two preceding weeks, rose again last week to 22, of which 12 occurred in Glasgow, five in Dundee, and three in Edinburgh. The deaths from whooping-cough, which had been 19, 17, and 20 in the three preceding weeks, were again 20 last week, and included 15 in Glasgow and four in Aberdeen. The fatal cases of measles, which had been 23, 19, and 12 in the three preceding weeks, rose again last week to 17, of which seven were registered in Glasgow, four in Greenock, three in Dundee, and two in Paisley. The deaths from small-pox, which had been one, one, and two in the three preceding weeks, further rose to seven, and included six in Glasgow and one in Perth. The fatal cases of diphtheria, which had been eight and three in the two preceding weeks, rose again last week to six, of which three occurred in Greenock. The deaths referred to different forms of "fever," which had been three, five, and 10 in the three preceding weeks, declined again to six last week, and included four in Glasgow. The deaths attributed to diseases of the respiratory organs in these towns, which had been 141, 173, and 211 in the three preceding weeks, further increased last week to 224, and were 47 in excess of the number in the corresponding period of last year. The causes of 21, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·7, 23·8, and 25·7 per 1000 in the three preceding weeks, further rose to 33·3 per 1000 during the week ending Feb. 22nd. During the past four weeks the death-rate has averaged 26·4 per 1000, the rates during the same period being 24·1 in London and 22·2 in Edinburgh. The 242 deaths of persons belonging to Dublin registered during the week under notice showed an excess of 55 over the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against four, five, and 11 in the three preceding weeks; of these, three resulted from measles, three from "fever," two from whooping-cough, two from diarrhœa, and one from diphtheria. These 11 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rates during the same period being 2·5 in London and 1·0 in Edinburgh The fatal cases of measles and of diarrhœa corresponded with the respective numbers in the preceding week, while the deaths from whooping-cough showed a slight decrease and those from "fever" an increase. The 242 deaths in Dublin last week included 39 of children under one year of age and 79 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a considerable excess over the numbers recorded in the preceding week. Four inquest cases and six deaths from violence were registered; and 101, or more than two-fifths, of the deaths occurred in public institutions The causes of eight, or more than 3 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

Surgeon Philip Nicholas Randall has been allowed to withdraw from His Majesty's Naval Service with a gratuity.

### ROYAL ARMY MEDICAL CORPS.

Major Richard E. Kelly is placed on temporary half-pay on account of ill-health. Dated Feb. 6th, 1902.

Lieutenant A. J. Williamson is placed under orders for South Africa. Lieutenant-Colonel E. Fiset, Canadian Army, joins the depôt at Aldershot for a course of instruction Surgeon-Lieutenant M. Cholmeley is posted to the 3rd Station Hospital, Aldershot, for duty.

Captain C. E. Pollock assumes medical charge of troops, Station Hospital, &c., Glencorse, vice Surgeon-Captain G. Melville, A.M.R.

### ROYAL ARMY MEDICAL CORPS (MILITIA).

The undermentioned gentlemen to be Lieutenants:—Hewitt John Lysaght Bullen and John White Hopkins.

### IMPERIAL YEOMANRY.

Nottinghamshire (Southern Nottinghamshire): The undermentioned officer resigns his commission and receives new commission, subject to the provisions of the Militia and Yeomanry Act, 1901, retaining his present rank and seniority: Surgeon-Captain H. Williams. Westmoreland and Cumberland: Surgeon-Captain J. E Bowser resigns his commission.

### VOLUNTEER CORPS.

*Rifle:* 2nd Volunteer Battalion the Essex Regiment: Brigade-Surgeon-Lieutenant-Colonel E. Shedd resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement, vacating at the same time the appointment as Senior Medical Officer to the Essex Volunteer Infantry Brigade

### ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Aberdeen Company: Lieutenant A. W. Mackintosh to be Captain. The Maidstone Companies: Captain C. P. Oliver to be Major, and to command under paragraph 55A Volunteer Regulations.

"these processes consist of subsidence and filtration, and the quality of the water delivered depends largely upon the thoroughness with which they are carried out?" Is the President of the Local Government Board aware that it is the duty of his department to ensure that "every company shall effectually filter all water supplied by them within the metropolis for domestic use before the same shall pass into the pipes for distribution"? Has the President of the Local Government Board ever caused any examination to be made of the water supplied from the Hanworth station of the East London Waterworks Company during periods at which the river was in flood? If he has not done so why has he not done so? If he has done so, when did he do so, and with what results?

## INDIAN PLAGUE COMMISSION, 1898-99.[1]

WE have to apologise for the delay which has occurred in the publication of our notice of this very exhaustive and important report and of the series of blue books connected therewith. All that we can fairly urge in explanation and mitigation thereof is to be found in such considerations as the nature of the task involving the consumption of much time and leisure in order to read the report and the difficulty of deciding as to the best method of arranging and expressing what we have to say on so large a subject in such a relatively small space as is at the disposal of a weekly journal to devote to it. We owe it to the President and members of the Commission and to our readers to state however that the length of our notice of these volumes is not to be taken as a measure of the time which we have given to the study of them. Still less should it be taken as fully expressing our opinion of the great value of the report and our high appreciation of the extent and very laborious nature of the work and duty undertaken by the Commission. In these respects it would be difficult to overestimate what has been accomplished for the report is so exhaustive that every point seems to have been considered and as far as it was possible to do so consistently with our present knowledge, the whole of the ground has been covered by the inquiry, with the result that the report will always take its place as a most valuable and scientific work of reference in connexion with the history of plague.

Since the advent of epidemic plague in China and India a great deal has been learnt as to what to do and still more, perhaps as to what not to do if we would steer clear of futility and needless sources of popular vexation and worry occasionally caused by public health measures. No one can read the report of the Commission without recognising that two of its striking features are the careful weighing of evidence and the *spirit of moderation* which it displays. Instead of seeking to reach some ideal standard which would be practically unattainable or recommending methods and procedures which would be well adapted to and could be effectively carried out in a scientific laboratory but would only prove vexatious and impracticable under the ordinary conditions of daily life the Commission has as it seems to us exercised much care and moderation in this respect. It has striven as far as possible, to avoid recommending a lot of measures which would prove an endless source of worry irritation, and unpopularity to the governing and governed classes alike and which in the end might not repay the cost of carrying them out.

The Commission had Professor T. R. Fraser, M.D., LL.D., F.R.S., professor of materia medica in the University of Edinburgh for its President with four other members and a secretary. Some idea may be formed of the formidable nature of the task undertaken and of the work done from the following fact. The report itself consists of 540 pages and with the minutes of evidence (printed in double columns) appendices summary, indices, and glossary, comprises five blue books containing altogether between 2000 and 3000 foolscap pages. The Commission arrived at Bombay on Nov. 26th 1898 and left India on March 25th 1899 after having made numerous journeys to places in that country where plague had prevailed and having personally initiated and conducted many bacteriological and other researches. During its inquiry in India the Commission held 70 sittings for taking evidence and examined 260 witnesses—without counting those who were recalled for examination. On leaving India arrangements were made, moreover, for carrying on and completing certain bacteriological and other investigations which were still in progress. It will be seen therefore that the Commission spared no pains to make its inquiries as searching and thorough as possible. The questions into which it was directed to inquire by the reference from the Government of India were:—(1) the origin of the different outbreaks of plague; (2) the manner in which the disease is communicated, (3) the effects of the curative serums of Yersin and Lustig respectively and (4) the effects of preventive inoculation.

The Commission was informed that it had been constituted for the purpose of conducting an investigation of a scientific character. It was found, however, that in the course of the inquiry a mass of evidence had been recorded which it was difficult to exclude but which could not be held to be strictly relevant to a purely scientific aspect of the subject. The Government of India while desiring that the scientific side of the inquiry should be the main one nevertheless accepted the necessity of taking evidence regarding facts of administration and left it to the discretion of the Commission to determine how far it was necessary to comment on the facts recorded in evidence. The report was to be not only for the information of the Indian Government but for that of other nations generally. The Commission was, in point of fact very wisely given a wide range of discretionary power as to the extent and conduct of its investigations and in the preparation of its report. The report is drawn up in two parts the first dealing in a somewhat amplified way with the four questions referred to, while the second part is devoted to a description of the measures actually adopted to deal with outbreaks of plague and to an inquiry about the possibility of making any improvement in them.

The general report is signed by all the members, but several subjects are taken up and discussed in separate and special memoranda furnished by the President and by some other members of the Commission respectively. The President in particular has put on record an able and valuable summing up and commentary on the evidence and his own conclusions in regard to many points which may we think be advantageously read and considered even by those who are wedded to a belief in the infallibility of a majority.

To take up and consider *seriatim* a number of points presenting themselves for review, as we had first thought of doing would extend our notice to great length. It would be futile to attempt to analyse an elaborate and voluminous report of this kind nor would it be doing justice to the labours of the Commission to select a very few points out of the numerous subjects and details which present themselves for consideration. The report must as it seems to us, be referred to and regarded as a whole in order to form any adequate idea of it. Happily it is well arranged and indexed and everything has been done that could be done for facility of reference. We can only speak of its general character. About this we do not think there can be two opinions. We have no hesitation in saying that the report is a very able exhaustive, and valuable public document. Whether people agree or disagree with everything laid down in it is after all, immaterial. The fact remains that no one interested in the subject of plague will be able to set aside such a mine of trustworthy, well considered information regarding the history of plague in India as these volumes afford.

## VITAL STATISTICS

### HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8341 births and 6959 deaths were registered during the week ending Feb. 22nd. The annual rate of mortality in these towns, which had been 17·9 20·6 and 22·6 per 1000 in the three preceding weeks, further rose last week to 24·4 per 1000. In London the death-rate was 29·3 per 1000, while it averaged 22·3 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 13·1 in Ipswich 13·4 in Derby and in Barrow-in-Furness, 14·2 in West Bromwich and 14·7 in Portsmouth, the highest rates were 29·7 in Wigan, 29·8 in Rochdale and ruined," as Major Ross terms it, or whether my punishment may not after a time be considered to have been sufficient.

---

[1] Report of the Indian Plague Commission with Appendices and Summary five volumes. Presented to both Houses of Parliament by command of His Majesty. London: Eyre and Spottiswoode. 1901. Price of Vol. V. (the Report) 4s. 6d.

I am, Sirs, yours faithfully,
G. W. P. DENNYS,
Lieutenant-Colonel I.M.S., Civil Surgeon.
Peshawar, India, Jan. 19th, 1902.

*To the Editors of* THE LANCET.

SIRS,—Everyone will admire the tone of Colonel Dennys's letter of Jan. 19th, 1902, and will admit the correctness of his own attitude in the matter. I hasten to explain, however, that he has misunderstood my intentions. I did not write my letter, published in THE LANCET of Dec. 21st, 1901, on his behalf personally. Had such been my object I should certainly have obtained his consent previously, either directly or through his friends, whereas I most carefully avoided doing anything of the kind. I wrote my letter, not in the interests of Colonel Dennys personally, but in the interests of justice and of the medical profession in general.

Colonel Dennys is quite right to acquiesce in the action of his employers, the Indian Government; but that is no reason why the rest of the profession should do so. Many of us have been long of opinion that the interests both of justice and of the medical profession have suffered by the action which the Government of India took in this case. We think that the punishment was an unjust one, and we have every right to say so.

In order to save any possibility of misunderstanding I repeat that I wrote what I did absolutely independently of Colonel Dennys. It is unnecessary to introduce the personal factor at all in the case.

I am, Sirs, yours faithfully,
Feb. 19th, 1902. RONALD ROSS.

⁂ In order that any remarks which Major Ross might wish to make should appear in the same issue of THE LANCET as that in which Colonel Dennys's letter was published, we sent a proof of that letter to Major Ross.—ED. L.

# THE DOSE AND LENGTH OF INCUBATION IN MEASLES AND VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—My attention has been called to a letter of Dr. L. C. Dobson, published in THE LANCET of Feb. 15th, p 477, upon vaccination, in which Dr. Dobson writes that with the exception of the Government establishment the only institute in or around London that manufactures its own lymph and which openly invites any member of the profession who may be interested in the process to inspect it for themselves is the Jenner Institute.

I have for the last 21 years manufactured my own lymph with signal success, during which time I have received testimonials from the medical profession in every part of the kingdom, whereas the Jenner Institute has, I believe, been only for some few years in existence. When THE LANCET Special Commission on Glycerinated Calf Vaccine Lymphs was appointed some years ago for the examination of bacterial purity of vaccine mine was placed at the head of the list.[1] I have always openly invited everyone, including, of course, members of the medical profession, to inspect my methods, and of this invitation a very large number of persons have availed themselves. I should not trouble you with this letter containing these statements about myself but for the fact that the publication of Dr. Dobson's statement in your columns would be an injustice to me if it passed uncontradicted. I shall therefore esteem it if you would kindly find space for this letter.

I am, Sirs, yours faithfully,
C. RENNER, M.D. Würzburg.
Marylebone road, N.W., Feb. 17th, 1902.

# THE DECAY OF AUSCULTATION AND THE USE OF THE BINAURAL STETHOSCOPE.

*To the Editors of* THE LANCET.

SIRS,—The introduction of the binaural stethoscope marked a distinct advance upon its single-stemmed progenitor. And although few would deny that the wooden instrument has its own special value, yet it will generally be conceded that the latter must take a back seat. It was related of some of the physicians at Guy's Hospital at the time of the introduction of the stethoscope that they were wont to show their contempt for the instrument by placing in it a flower and carrying it so decorated through the wards—the stethoscope, however, had "come to stay." A man does not surely see less distinctly by using both eyes, neither is the use of two ears a disadvantage in auscultation. In the binaural stethoscope we have the advantages of both immediate and mediate auscultation combined. This can be seen by a simple experiment. Place the chest-piece of a binaural stethoscope on a watch and on listening the ears will, as it were, be taken to the source of the ticking, while if one tube be occluded by pinching it the sound is heard at the other ear, not at the watch as in the former observation. I am not aware that this point has been noticed generally. I think that most careful auscultators avail themselves of both instruments in doubtful cases, as I certainly do myself, though for convenience the binaural is most frequently resorted to. There can be no question that the pressure of a stem stethoscope may cause much suffering to the patient, whereas pressure is not only unnecessary but harmful with the binaural variety. The pain caused by frequent pressure of ivory ear-pieces can easily be avoided by the use of india-rubber ones.

I am, Sirs, yours faithfully,
Weymouth-street, W., Feb. 21st, 1902. CHAS. W. CHAPMAN.

# "WHAT'S WHAT."

*To the Editors of* THE LANCET.

SIRS,—As soon as I was aware that my name had been mentioned in "What's What" I wrote to the editor and I send you a copy of my letter and of his reply.

I am, Sirs, yours faithfully,
Feb. 24th, 1902. ANDERSON CRITCHETT.

[INCLOSURES.]

Harley-street, Feb. 15th, 1902.

DEAR SIR,—My attention has been called to the fact that in a book called "What's What," of which you are the editor, my name is mentioned in a manner which is likely to be misunderstood by the public and by the members of my profession. I have always strongly deprecated, and have done my best to avoid, any personal allusions in the lay press, and although I willingly acquit you of any intention to do me an injury I must beg that in any future editions of your book my name may be omitted.

Faithfully yours,
Harry Quilter, Esq. ANDERSON CRITCHETT.

9, Manchester-square, W., Feb. 18th, 1902.

DEAR SIR,—I beg to acknowledge your letter of the 15th, forwarded to me last night. If you will refer to either THE LANCET or the *Medical Journal* of last week you will find a letter from Mr. Watson Cheyne to myself on the same subject as your communication and my reply thereto. This will show you that I shall not in future be likely to repeat the atrocious crime of which you so pathetically complain. I much regret that in my desire to convey certain information to the public I should have caused any vexation by my allusions to special medical practitioners.

Yours faithfully,
HARRY QUILTER.

# THE DISSEMINATION OF KNOWLEDGE CONCERNING VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—At the meeting of the Sanitary Institute last week, at which an interesting paper on the Prevention of Small-pox in the Metropolis was read by Mr. A. Wynter Blyth, medical officer of health of St Marylebone, it was not suggested that the public should be made acquainted with the facts concerning vaccination by means of popular lectures. The meetings of the Sanitary Institute, excellent as they are, are practically unknown to the general community. I would suggest that the Sanitary Institute, the National Health Society, the St. John Ambulance Association, the Royal Institution of Public Health, and the Incorporated Society of Medical Officers of Health should arrange that lectures should be given stating the facts in a popular and simple manner, and giving statistics (obtained from the present epidemic in London and from other former outbreaks) to prove the advantages resulting from efficient vaccination. To be effective the lectures must be given all over the country. Medical officers of health could themselves diffuse information in a similar manner. I am aware that some have already done so. Lantern-slides showing the typical course of vaccination, similar to the coloured plates published in the "Jenner Number" of the *British Medical Journal* of a few years ago, would be most useful. Also photographs to show what a real case of small-pox is—"modified," "confluent,"

---

[1] THE LANCET, April 28th, 1900, p. 1234.

### Volunteer Infantry Brigade.

Essex: Surgeon-Captain H. T. Challis, 4th Volunteer Battalion the Essex Regiment, to be Brigade-Surgeon-Lieutenant-Colonel on appointment as Senior Medical Officer to the Brigade.

### South African War Notes.

Civil Surgeons Coffey, Laing, McDougall, Odonovan, and Lynch have been discharged from hospital to duty.

Lieutenant F. H. Merry, R.A.M.C. (invalided), Major H. J. Fletcher, R.A.M.C., and Civil Surgeons White (invalided), David (invalided), Leaming, Harris, and Wright are returning to England in the *Orient* which left Cape Town on Feb. 13th.

Captain E. M. Pilcher, R.A.M.C., Surgeon-Captain Joynt, Scottish Horse, and Civil Surgeons Clarke and McLelland are on passage home.

### An Ancient Ordinance dealing with Ship-Surgeons.

In France, says a writer in the *Archives de Médecine Navale* for January, it was customary to look upon the Royal Ordinance of August 4th, 1819, as the first real mark of solicitude on the part of the State for the health of its seafaring population, but according to an ancient "Règlement," of which a copy is printed by our contemporary, the abovementioned date is at least a century too late. The document in question, which is very quaintly spelt, consists of a preamble with nine articles, and is signed "Louis, par le Roy, le Duc d'Orleans Regent, present Phelypeaux." The date of promulgation of this law was June 5th, 1717, and it deals with the provision of "Chirurgiens" for merchant vessels, together with the mode of examination of candidates for such appointments. In the preamble "H.M. Louis, by the Grace of God King of France and of Navarre," informs all and sundry that in spite of the Ordinance of "Aoust, 1681," the people who act as surgeons at sea are no better than ignorant impostors who imperil the health and well-being of his faithful subjects. For the future, therefore, no one shall be permitted to embark on board a sea-going "bastimen" in the capacity of surgeon who has not been examined by two master surgeons and found qualified. Every vessel with a crew of 20 men and upwards shall carry a surgeon, and when the crew number more than 50 there must be at least two surgeons. For each examination the master surgeons shall receive five livres, "to divide between them," but if the vessel on which the candidate proposes to embark is of less than 150 tons burden the fee shall be reduced to three livres. Pains and penalties of various kinds are provided in case a grasping master surgeon should try to extract more, save and except in the event of his being required to inspect the surgeon's medicine chest, when he can demand 20 sols, a similar sum being payable to his coadjutor an "apoticaire."

### The Report of the Ladies' Committee on the Concentration Camps.

The report of the Ladies' Committee on the Concentration Camps in South Africa is, we need scarcely say, very much what might have been anticipated by all "level-headed" people. Great care was exercised in the selection of the members of the committee. It was not to be expected that they would find everything perfect everywhere they went, but their report is very satisfactory nevertheless. There is no doubt that a large amount of sickness, attended with a heavy mortality, occurred in these camps, more especially among the Boer children, but, however much this may be deplored, it was inevitable under the circumstances. The Boers deserted their families in order to fight against us, and the British authorities in the field out of humanity undertook the care of them rather than allow them to perish on the veldt. The Boers neglect the most elementary principles of hygiene and their notions of treating the diseases of childhood are worse than antiquated. The responsibility and difficulty of undertaking the care of their families were immense under such circumstances. All the stories about the camp hospitals are simply untrue. It will be curious to see how those who raised a protest against, as they allege, the wholesale murder of women and children will deal with this report of the Ladies' Committee.

### Recruiting for 1901.

The annual report of the Inspector General of Recruiting for 1901 is on the whole satisfactory. The total number of recruits for the regular army was 47,039, and for the militia 37,644. Speaking generally, recruiting for the first half of the year fell off, but it improved very much during the second half, the year's total being only 2000 below that reached in 1900, when the enthusiasm about the war in South Africa was in full force. The inspector-general's report contains a number of comments and remarks which have a distinctly medical bearing, such, for example, as the numbers medically inspected and rejected, the loss to the service of recruits owing to defective teeth, and so forth. We are glad to notice that the inspector-general strongly advocates the provision of suitable houses for recruiting purposes—a subject to which we have frequently drawn attention. Buildings, instead of being in slums and back streets, should be secured in more open, airy, and prominent thoroughfares than are now provided for the examination of recruits, and they should be properly furnished and equipped so as to be more attractive to young men than is at present the case; and if something could be done in the way of abolishing the system of "stoppages" it would, we think, have a good effect on recruiting.

### The Army Estimates.

Referring to the recently issued Memorandum of the Secretary of State for War relating to the Army Estimates for 1902–3 we may state that the sum-total amounts to £69,310,000, while the number of men to be voted is 420,000. This shows a financial reduction of over £23,500,000 as compared with last year. This reduction is mainly to be accounted for by a decreased provision for war services in South Africa and China. As regards Vote II., Medical Services, the decrease on the vote amounts to £63,600, of which £50,000 are for war and £13,000 for normal services.

### Volunteer Officers' Decoration.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officers:—*North-Eastern District: Artillery:* 1st West Riding of Yorkshire (Sheffield) Royal Engineers (Volunteers): Surgeon-Lieutenant-Colonel George Robinson. *Scottish District: Artillery:* 1st Ayrshire and Galloway Royal Garrison Artillery (Volunteers): Surgeon-Lieutenant-Colonel James Thomson. *Western District: Artillery:* 1st Cornwall (Duke of Cornwall's) Royal Garrison Artillery (Volunteers); Surgeon-Lieutenant James Mudge, jun.

## Correspondence.

"Audi alteram partem."

## A QUESTIONABLE PUNISHMENT.

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of Dec. 21st last (p. 1762) Major Ronald Ross, I.M.S. (retired), has addressed a letter to you under the above heading. I happen to be the civil surgeon to whom he refers in that letter and about whom he wishes to obtain the opinion of your readers "with a view to further action if deemed necessary." Though I fully appreciate the kindly motive that has prompted him to take this action on my behalf I feel I cannot allow the matter to go further without recording my most emphatic protest at any action whatsoever being taken by the medical profession in this matter.

Whatever may be the opinion of medical men in general as to the justice of the punishment that has been meted out to me by the Indian Government for the slip of the pen I was guilty of some years ago when writing a prescription, I have to recognise the fact that the punishment must have met with the approval of the head of the Indian Medical Service, who is their adviser in all matters concerning members of my service, and so long as I continue to serve under the Government of India it is obviously my duty to be loyal to that Government and to abide by its decisions.

I think I might mention in this connexion that a great deal more harm has been done to me by the efforts of my friends to be kind than ever would have occurred had they only left me alone. I am content to leave my future career in the hands of the Government under whom I serve with perfect confidence, and wish for no outside interference. It remains yet to be seen whether that career is "entirely

# SCIENTIFIC EXPERIMENTS IN HOUSE VENTILATION.

(From our Special Sanitary Commissioner.)

Any new suggestion in regard to ventilation is always welcome, but what is more particularly needed is some practical method of ventilating private houses. A theatre or a large assembly room costs so much to build and to keep in working order that it is comparatively easy to include in the outlay the expense necessary to secure more or less efficient ventilation. This is not the case with regard to the private house, and the problem will not easily be solved unless those concerned are willing to add to the ordinary cost of a private dwelling the cost of a scientific system of ventilation. Nevertheless, it is something to know that such a system can be worked satisfactorily even in the restricted space of a small room. Dr. Thomas Glover Lyon and Mr. James Cadett have between them devised and applied such a method. The experiment in question has been carried out in a small dining-room built over what used to be the back-yard of a house in a central and crowded part of London. Dr. Lyon showed and explained the details. Taking the Vienna Opera House as his model he calculates that each person should be supplied with 1600 cubic feet of fresh air per hour, and this cannot possibly be done regularly and in all weathers unless mechanical means are employed. He reckons that 12½ cubic feet of air weigh one pound. Therefore a theatre seating 1000 people will require 1,600,000 cubic feet per hour, or about 450 cubic feet per second, and this would correspond to 50 tons per hour or 30 pounds per second. To move this amount of air a 10 horse-power engine would be required or thereabouts. A private room, therefore, holding 12 persons, would need 19,200 cubic feet of fresh air and a motive power equal to moving one and one-eighth of a ton per hour. This is not to be obtained by the mere difference of indoor and outdoor temperature and the currents of air that result therefrom. Also, such currents, instead of being uniform, always vary in velocity according to the fluctuations in the temperature. For ventilation to be perfect doors and windows must be shut and no air admitted save that which is pumped into the room, and then only is it possible to supply precisely the proper quantity at the desired temperature. It is on these principles that the dining-room in Dr. Lyon's house has been ventilated. This work has been greatly simplified by the fact that the roof is immediately above the ceiling and that it is not necessary to go to the top of the house or to pierce the outer walls to find fresh air. Nor are there any windows in the walls. The light comes from the glass panes of a lantern above the centre of the room. Outside there is a small compartment large enough to hold an engine, an electrical apparatus, the propelling fan, and the trays for washing the air. The latter are placed in a sort of cupboard with the air inlet protruding on the roof above, which has to be protected in such a manner as not to be clogged up by a downfall of snow. As the air penetrates and descends it strikes upon and has to travel zigzag between a succession of long trays filled with mineral oil. This oil arrests the dust, the soot, and other heavy particles borne forward with the air. For such a purpose oil is preferable to water, as the particles sink to the bottom of the oil, whereas capillary attraction keeps a large portion of them floating on the top of water. Moreover, if water is employed it will evaporate and perhaps render the air too moist. Below the trays, against which the air must strike at least twice, there are hot-water coils to warm the air, and beyond is the fan. According to the velocity at which this fan revolves more or less air is drawn from outside the roof down on to the washing trays and the heating coils, and is then propelled into the duct for distribution in the room beyond. This duct being measured an anemometer placed inside will record the velocity at which the air travels and the number of cubic feet supplied can thus be accurately estimated. A few experiments will show at what rate the engine must work in order to provide the amount of air needed. Any sort of motive force to work the fan could be employed, but for private houses electricity is to be preferred because it is clean, produces the least noise, and can be turned on or off at once and just when it is wanted. For a small room the cost of electric power will not amount to more than 1d. per hour.

The cleaning, the warming, and the supplying of the right quantity of air constitute, however, only the minor or least difficult part of the problem. By far the most perplexing phase is to know how to distribute this air in the room in such a manner as not to inconvenience the persons within. For this purpose it does not suffice to have large inlet surfaces, for it would then be found that the air would come through one portion of these apertures with great velocity and hardly at all from the other parts of the openings. Therefore it is necessary to study and to ascertain where the current is strongest and there to place the greatest number of obstacles. For instance, in Dr. Lyon's dining-room there is a conduit or shaft running along within the top of a false inner wall. The impetus given to the air by the fan is such that it will travel in a straight line to the end of the conduit and not avail itself of the apertures on the road to enter the room. It is therefore by the opening nearest to the end of the conduit, where the air can no longer travel forward in a straight line, that the greatest amount would escape into the room. To meet this difficulty false inner walls have been built on two sides of the room, facing each other, the one to serve for the inlet and the other for the outlet of the air. This adds considerably to the complication and expense of the system, but it lends itself admirably to decorative purposes. The false wall, which can be made of wood, should stand six inches in front of the real wall. Only a portion of this space, six inches deep, is required for ventilation, and the rest can be employed for real cupboards or for bookshelves. The part used for ventilating purposes has the appearance of closed cupboards, about two feet wide and four feet high, and there are three of them on each of the two sides of the room which have false walls. Pilaster or panelling can be employed for these false cupboards, but behind this ornamentation there must be a perforated shutter or a wire gauze. These perforations being the same in all parts of the shutter or wire gauze, the air would not come through evenly from the entire surface but would rush out with greater velocity from that part of the cupboard or air-chamber where the pressure was greatest. Here, then, the same principle applies as that mentioned with regard to the air-conduit which runs horizontally along the room near the ceiling. In this case, however, the air propelled or pressed out of the horizontal conduit receives an impetus that makes it travel downwards in a vertical line to the bottom of the cupboard. There it is abruptly checked and begins to expand. It is consequently from the bottom of the cupboard that the largest quantity of air would come out into the room and perhaps create a draft. Therefore a baffling arrangement must be placed behind the shutter to counteract this tendency. For this purpose narrow slips of wood are fastened to the inside of the shutter. These slips are in the shape of very long and acute triangles. The triangles are placed with their broader part or base at the bottom of the shutter and they nearly touch each other, so that the apertures between them are smallest just where the pressure of the air is greatest, and become wider and wider as the upper part of the cupboard is reached. Thus between these four letters A A A A the space is much wider at the top than at the bottom; but we must imagine these angles to be much longer and narrower than is the case with ordinary type letters. The principle applied within each cupboard is also applied with regard to the relationship of the cupboards the one to the other. Therefore, at the inlet end of the air conduit—that is, where the air passes with the greatest impetus or velocity and is less likely to be diverted from its course so as to enter the air-chamber or cupboard—there the cupboard is largest and offers the least resistance. At the other end of the conduit, where, on the contrary, the air is suddenly stopped and can travel forward no further but must find some other exit, there the nearest chamber is the smallest and offers the most resistance. The pressure varies all along the conduit and inside the cupboards in consequence of the continual conflict between momentum and pressure. Hence the necessity of providing the largest outlets where the pressure is most feeble.

Having ensured by the means described that the velocity of the delivery of the air shall be uniform over the entire surface of the apertures, the next question to consider is what the air will do when it has entered the room. For the air outlets there are similar air-chambers or cupboards on the opposite side of the room, only the baffling triangular pieces "malignant," and "hæmorrhagic." These slides will bring before the public what it cannot otherwise form an opinion of, and they need not be made revolting in their character. They cannot be more terrible than the disease itself. Such representations of actual facts will do more to convince people than pages of written matter. If it is "brought home" to them how loathsome and dangerous a disease small-pox is, and how easily it can be stamped out by vaccination and with so infinitesimal a risk by this process, the anti-vaccinator will similarly be "stamped out" in time. The chairman at such lectures should be a gentleman whose name in the scientific world is well known, or some local magnate whose influence will carry weight with the audience.

I shall be pleased to lend my lantern for the purposes of such a lecture to any medical officer of health.

I am, Sirs, yours faithfully,
HERBERT W. G. MACLEOD, M.D. Edin.,
London, Feb. 23rd, 1902. D.P.H. Cantab. and Lond.

## SURGICAL OPERATIONS FOR MITRAL STENOSIS.

*To the Editors of* THE LANCET.

SIRS,—In reference to the correspondence in your columns with regard to Sir Lauder Brunton's preliminary communication upon the above subject, I can corroborate Mr. Arbuthnot Lane's statement that he and I fully discussed the matter at least 12 years ago. Mr. Lane introduced the subject to my notice and satisfied me that he probably could without any immediately harmful result temporarily enlarge, by surgical means, the orifice of a constricted mitral valve. Lest, however, it should appear from Mr. Lane's letter that I am still hoping to succeed "in finding a case likely to receive benefit" therefrom, I shall be obliged if you will allow me to state that the *à priori* arguments against the probability of any patient deriving benefit from this operation seemed to me so conclusive that I deliberately decided against regarding it as a justifiable therapeutic measure. These arguments are so clearly summarised in your leading article of Feb. 15th (p. 461) that your readers will, I think, agree with me that Sir Lauder Brunton's chief task is not to show his surgical colleagues that it is possible to enlarge the stenosed mitral orifice, but to persuade his medical colleagues that such a proceeding is useful. It is possible to do many things that are useless and some things that are harmful.

I am, Sirs, yours faithfully,
Harley-street, W., Feb. 25th, 1902. LAURISTON E. SHAW.

## BIRMINGHAM AND DISTRICT GENERAL MEDICAL PRACTITIONERS' UNION, EAST BIRMINGHAM BRANCH.

*To the Editors of* THE LANCET.

SIRS,—I have the honour to forward to you herewith a copy of resolutions recently passed by the above body which are self-explanatory.—I am, Sirs, yours faithfully,
H. W. POOLER, Honorary Secretary.
Great Brook-street, Birmingham, Feb. 19th, 1902.

[INCLOSURE.]

*Birmingham and District General Medical Practitioners' Union, East Birmingham Branch.*

The following is a copy of a resolution passed at a meeting of the above society held on Jan. 9th: "That the honorary secretary be instructed to write to the managers of the various medical aid societies working in East Birmingham and inquire whether they are prepared to adopt the course of action already adopted by the National Medical Aid Company and the London and Manchester Medical Aid Society, which societies have resolved under no circumstances whatever to admit new members or to re-enter lapsed ones, and, further, that the result of the correspondence be reported to the next meeting."

At a meeting held on Feb. 13th, 1902, the honorary secretary reported that each of the societies concerned had given a written guarantee to observe the conditions laid down in the above resolution and it was thereupon further resolved:—

"That this meeting is of opinion that the undertaking given by the managers of the various medical aid societies which are working in East Birmingham is perfectly satisfactory and calculated to deal effectually with the practice of canvassing; and, further, that this meeting trusts that the medical officers and managers of these societies in East Birmingham will take care that this undertaking is rigorously carried out."

"That this meeting is of opinion that the establishment of private medical clubs is not in accordance with the real interests of the public, is derogatory to the dignity of the medical profession, and is eminently unfair to those medical aid societies which have given undertakings not to accept new members, and, further, that all possible means will be taken to prevent the formation of such private clubs in East Birmingham."

"That copies of these resolutions be forwarded to each of the medical aid societies, to the council of the Union, and to the medical press."

## THE NEW DESIGNATION FOR THE VOLUNTEER MEDICAL STAFF CORPS.

*To the Editors of* THE LANCET.

SIRS,—Your correspondent in THE LANCET of Feb. 22nd, p. 547, hardly does the volunteer medical officer justice when he states that 11 are serving with the Royal Army Medical Corps, because a number of volunteer medical officers, realising how difficult it was unless they belonged to a bearer company to get their services accepted, have joined as civilians and obtained a higher rate of pay. The great obstacle to the discarding of compound ranks is the regimental system which follows exactly that of the various regiments of Guards, and the War Office has an idea that it is the wish of the regimental medical officers to remain so in order that they may still continue to wear the uniform of their regiments. My idea is that directly a regimental medical officer is gazetted he should become an officer in the Royal Army Medical Corps (Volunteers), and should wear departmental uniform; he is then always distinguishable and in the uniform for regimental or departmental duty. I will be glad if all volunteer medical officers will send me a postcard stating whether they agree or do not agree with my proposal. I will tabulate and publish the result and get the same presented to the Under Secretary of State for War.

I am, Sirs, yours faithfully,
P. B. GILES,
Brigade Surgeon Lieutenant Colonel S.M.O. Volunteer Ambulance School of Instruction.
Bletchley, Feb. 24th, 1902.

## TREATMENT OF RESPIRATORY INCAPACITY.

*To the Editors of* THE LANCET.

SIRS,—I shall be obliged if you will kindly find space to correct a misprint that somewhat confuses the meaning of the first sentence of the article on Cleft Palate in THE LANCET of Feb. 22nd, 1902, p. 493. Instead of "treatment of the sufferers from cleft palate" the words should read "treatment of the sufferers from respiratory incapacity."—I am, Sirs, yours faithfully,
Cavendish-square, W., Feb. 24th, 1902. W. ARBUTHNOT LANE.

## TETANUS FOLLOWING REVACCINATION.

*To the Editors of* THE LANCET.

SIRS,—I have read with interest the case of tetanus following revaccination on the leg in your issue of Feb. 22nd. With all due deference to the authors the most likely source of contamination does not seem to have been considered. After all their careful antiseptic measures they covered the wound with a "bunion plaster" and fixed this on with adhesive plaster. This would seem to be an ideal way of conveying tetanus and any other infection. I trust that public vaccinators as a rule follow their instructions more carefully and use an antiseptic dressing.

I am, Sirs, yours faithfully,
Feb. 23rd, 1902. ONE OF THEM.

---

ROYAL MICROSCOPICAL SOCIETY.—At a meeting of this society held on Feb. 19th a very short paper on Polarising with the Microscope by Mr. E. M. Nelson was read by the secretary in the unavoidable absence of the author. The object of the paper was to recommend the employment of tourmalines in place of Nicol's prisms, both in the ordinary examination of polariscope specimens and in the production of rings and brushes. It was recommended that the polarising tourmaline should be placed not below the stage but close to the lamp, and that the analyser should be set in a cap which fitted over the eyepiece. One of the members who spoke subsequently remarked on the great difficulty of obtaining tourmalines sufficiently free from colour.

of Poor-law Unions held in London on Feb. 20th the Mayor of Cardiff, who is a member of the board of guardians, expressed the opinion that the fees were altogether too high and that if they were not reduced the Cardiff board was prepared, with the assistance of other boards, to take steps to secure a reduction. The members of the Cardiff board do not appear to realise that the fees payable under the Vaccination Act, 1898, are for services which are of a very responsible character and in the proper performance of which a great deal of time is expended. If the definite instructions of the Local Government Board with regard to the aseptic precautions which are to be taken by the public vaccinator when performing the operation are to be properly carried out an adequate fee must be paid by the authority responsible for payment.

### *Merthyr General Hospital.*

The Merthyr General Hospital was established in 1887 and has accommodation for 29 patients. The annual report of the executive board which has just been published is of a very satisfactory character, for it discloses the fact—a very unusual one in connexion with public hospitals—that extensive additions have been made to the nurses' home and electric light has been installed in the operating theatre without making any special call upon the supporters of the hospital and without encroaching upon the invested funds. During 1901 there were treated in the wards of the hospital 212 patients. The average weekly cost per patient is not stated.

### *Lodgers in Small Houses.*

At the recent assizes for the county of Monmouth Mr. Justice Phillimore in his charge to the grand jury drew their attention as magistrates and landowners to the dangers of the presence of lodgers in the small houses of working people and said that it looked as if much crime was due to the influence of lodgers upon the wife and children of the house. It is difficult for those who do not live among them to realise how many of the colliers in Glamorganshire and Monmouthshire live in "apartments." In the last annual report of the medical officer of health for the Rhondda valleys he states that among 2414 houses specially inspected there were 1242 in which lodgers were taken. There can be little doubt that the high death-rates which prevail in the colliery districts are closely connected with the overcrowding of the houses in these localities.

### *Wiltshire County Council.*

The parish of Westwood in Wiltshire has a population of about 500 persons who are very indifferently supplied with water from wells, and the sanitary authority—the Bradford-on-Avon Rural District Council—cannot be persuaded to take steps to improve the supply. The Wiltshire County Council has therefore given notice that if a proper supply is not provided within six months action will be taken under Section 16 of the Local Government Act, 1894. This section enables a county council, after complaint by a parish council of the default of a rural district council to carry out certain duties, to transfer those duties and the accompanying powers either to the county council or to some one person with instructions to carry out the duties of the defaulting district council.

### *The New Workhouse Dietary.*

The cost of the new dietary at the Frome Workhouse for the half-year ending Dec. 31st, 1901, was 3*s.* 6*d.* per head weekly (including special infirmary diets), and for the same period of 1900 (with the old dietary) the average weekly cost per head was 2*s.* 8*d.* The population of the Frome union is about 20,000 and the workhouse will accommodate 400 inmates.

### *Bath Eye Infirmary.*

The annual meeting of the Bath Eye Infirmary was held on Feb 21st, when it was reported that there was an adverse balance on the year's working of £25 in spite of the receipt of a special donation of £61 from the committee of the Bath Hospital for Women, an institution which is now closed. During 1901 there were treated at the infirmary 295 in-patients and 1898 out-patients. The Bath Eye Infirmary was established in the year 1811.

### *Death of Mr. C. E. G. Simons, M.B., C.M. Aberd., D.P.H.*

Through the death of Dr. Simons of Merthyr Tydfil, at the early age of 34 years, there has been lost to the medical profession one who gave promise of becoming noted in the public health world. For several years he was associated in practice with his uncle, the late Mr. T. J. Dyke, F.R C.S. Eng., who was the first medical officer of health for Merthyr Tydfil and the second medical officer of health to be appointed in the whole of England and Wales. For a few months Dr. Simons held the same position in Merthyr Tydfil, but gave up the post chiefly on account of ill-health. He died on Feb. 16th from pneumonia, though for some years he had been suffering from diabetes. He leaves a widow and two children.

### *Vaccination as Poor-law Relief.*

At the meeting of the Newton Abbot Board of Guardians held on Feb. 19th some of the guardians said that persons who were revaccinated by the public vaccinator became paupers. The clerk, however, stated that vaccination did not constitute parochial relief, and eventually the board decided to issue notices to the effect that revaccination would be performed free of charge.

### *Royal Devon and Exeter Hospital.*

The court of governors of this institution was held on Feb. 20th, under the presidency of the Bishop of Marlborough (Dean of Exeter). The medical report stated that 1258 in-patients had been treated during 1901, compared with 1219 in the preceding year. 5103 out-patients were treated, against 5067 in 1900. The average daily number of in-patients was 146. The financial statement showed that the total receipts for the year had been £14,825, which included £8390 from legacies. The total expenditure amounted to £9777. The Bishop of Marlborough was re-elected president for the ensuing year.

Feb. 24th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Proposals for a Psychiatric Clinic in Edinburgh.*

A SPECIAL meeting of the Edinburgh Medico-Chirurgical Society was held on Feb. 19th in the hall of the Royal College of Physicians of Edinburgh to discuss the question of having wards in the Royal Infirmary set aside for the treatment of incipient and transitory cases of mental disorder. The meeting was held at the instigation of some of the more prominent alienists in Edinburgh and was attended by a number of laymen and by several ladies. Looking at the audience gathered on this particular occasion it could not have been inferred that the subject was one in which the local profession was deeply interested. While the meeting was nominally a meeting of the Medico-Chirurgical Society it would be presumptuous to regard its decision as the deliberate finding of the society. The alienists naturally took the most prominent part in the discussion of their own scheme. The general opinion seems to be that it is desirable to have accommodation for this special class of case in the Royal Infirmary, but it is felt that the annual sum required for the upkeep of the infirmary is already so large that the managers can hardly be expected to rush into the matter. At present there is neither building nor ground available for the purpose, and until some rich friends of the promoters come forward with an endowment the infirmary managers will have public feeling with them in taking up a position of sympathetic *laissez faire.* Another point which finds expression in the profession, although no voice was given to it at the meeting, is that if such wards ever are established they ought to be under the charge of one of the general physicians to the infirmary and not under a specialist. Part of the object in having such wards is to avoid the stigma attached to a person who is sent to an asylum, and it is seen that if a prominent alienist was in charge the wards would be looked upon by the public as the "mad wards" and as being under the care of a "mad doctor," and that the stigma would thus be as great as attaches to being sent to an asylum. The raising of the question may have an immediately good result in leading the managers to relax the present rules regarding the exclusion of persons showing any measure of mental derangement. Two of the members of the infirmary staff referred in the discussion to these rules and they might with advantage be relaxed so that the admission of threatening cases of mental derangement, associated as they so often are with physical disturbance, might be left to the judgment of the individual physician.

### *Public Health: the Examination of Pathological Products in Edinburgh.*

Within the past few weeks there has been a good deal of of wood are placed in the reverse way The inlet apertures are largest at the top of the cupboards and if the outlet apertures were similarly disposed then the air would simply travel across the upper portion of the room Consequently the broad bases of the triangles are placed at the top of the outlet cupboards and the widest openings are at the bottom The hot air being propelled downwards as it enters it meets the colder air and these two currents tumble over each other and create a rotary motion in the centre of the room This prevents stratification or the forming of layers of atmosphere, some of them moving rapidly and others slowly or not at all, and thus efficient ventilation is secured for all parts of the room Communicating with the outlet cupboards there is also a horizontal conduit leading to a second fan which, revolving in the reverse way acts as an exhaust and throws the air out above the roof, but at a point situated as far as possible from the inlet

The air, though delivered in great volume and at considerable velocity, is so baffled and evenly distributed that its passage cannot be felt The room may be filled with people smoking but the smoke is at once carried away the atmosphere remaining always clear and fresh This is a great comfort and the active ventilation has a distinct effect on the appetite of the people dining But it will be seen that these results are not attained without considerable trouble expense and minute attention to detail It is doubtful if this system could be applied to a room for much less than £150 There are not many persons who could afford such an outlay Dr Lyon however replies to this objection by supposing that some wealthy person was in the habit of giving dinners with on an average 20 guests at a cost of about £2 per head It would suffice to give three dinners less than usual to provide the means of defraying the cost of such a system of ventilation and ever afterwards the dinners given would be infinitely more enjoyable

## MANCHESTER

(FROM OUR OWN CORRESPONDENT )

### *Manchester Royal Infirmary*

AT the annual meeting of the trustees of the Manchester Royal Infirmary held on Feb 14th Sir Forbes Adam the chairman said that the most important part of the report related to the sub committee appointed nearly a year ago to form plans for the rebuilding of the infirmary on the present site He said that it had been reported to them by a previous meeting that a hospital on the non pavilion plan would be in every respect satisfactory The great majority of the authorities while still of opinion that the ideal plan was the pavilion plan saw no reason why if under the circumstances it was not possible to have on the site a pavilion hospital there should not be an absolutely satisfactory hospital on a plan other than the pavilion plan "The sub committee hoped very soon to hand their report to the board and it would be considered by the board in conjunction with the medical board and with any other competent expert outside gentleman whom the board might think fit to join them in their deliberations A new infirmary has long been needed and the medical board some time ago declared it to be a public scandal that Manchester should have no better hospital accommodation than the existing one That point is settled but the question of site may, perhaps even yet be open to discussion Authorities accept the pavilion plan as the ideal and any other is confessedly inferior to it There is no room on the present infirmary site for the ideal the pavilion hospital so that if it is rebuilt where it now stands Manchester must accept and try to be content with something below the best—i e, with an inferior hospital Yet according to Sir Forbes Adam the authorities see no reason why an inferior hospital should not be absolutely satisfactory which seems a *reductio ad absurdum* No one supposes that if there were sufficient space on the present site any but the pavilion plan would be entertained for a moment Insufficient space is driving all concerned to the adoption of an "absolutely satisfactory' inferior plan The chief reasons for the strong feeling on the part of many in favour of the present site are that it is central and of easy approach from the various railway stations, that it is on the whole as convenient as any other for the medical staff, and that it has stood where it now stands for a long time so that sentiment has grown up around it There are however, many objections to the Piccadilly site The space about it is so scanty that the wards are not far enough away from the surrounding streets busy with noisy traffic from early morning till late at night To many patients the noise especially with open windows is most distressing and there is no escape from it Then too the fog in the centre of the town is often dense to a degree and singularly pungent and choking causing injury with much distress in breathing and coughing to those suffering from chest ailments The financial question is also an important one If the infirmary is to be rebuilt where it now stands the money required will have to be raised where there are already numerous charitable calls, where almost all the hospitals are in debt and where their reports are full of grievous lamentations over the customary annual deficit Should however, another site be chosen as for example that of Stanley Grove the sale of the Piccadilly site would provide funds for rebuilding without having to ask the expert outside gentleman to solve the problem of how to get an absolutely satisfactory hospital by an inferior method As regards the financial position the institution on its present basis shows a surplus but as the chairman regretted to say it was entirely eaten up by the deficit on the Barnes Convalescent Home

### *Teaching to Check Infantile Mortality*

The Cheshire County Council is doing a good work in one branch of education At the quarterly meeting held on Feb 13th the chairman of the Technical Instruction Committee said that 46 scholarships in physiology and infant hygiene had been granted the object being to give good and thorough instruction in these subjects to mistresses of elementary schools so as to qualify them to teach them in day and evening schools, in the hope of overcoming the ignorance which prevailed as to the feeding and proper care of infants It was mentioned that at Hyde where the infant mortality has been high several of the mistresses had taken scholarships and it was hoped that mistresses from the adjoining towns of Stalybridge and Dukinfield would do so At Sandbach National School this teaching forms a special subject

### *Arsenic in Beer*

At the same meeting of the Cheshire County Council the report of Mr Carter Bell the county analyst stated that the beers which he had analysed were practically free from arsenic In some cases they contained from $\frac{1}{500}$th to $\frac{1}{300}$th part of a grain to the gallon so that a person would have to drink 300 gallons to obtain one grain of arsenic

### *Red Lead in Beer*

At the Manchester Police court on Feb 17th a man was charged with wilful and malicious injury to property by putting a quantity of red lead into a brew of beer valued at £60 He had had notice to leave When charged he said that he had done it "not with the intention of poisoning anyone but simply to spoil the reputation of the brewer This would seem to be a sufficiently serious matter and one cannot well see any room for much sympathy towards the offender But the prosecution and the bench were apparently alike tenderly disposed to the prisoner who had the grace to say that he was ashamed of the wrong done and as is customary asked for mercy for the sake of his wife and child and aged parents The chairman of the magistrates said that he had taken a very *stupid* feeling against the brewer and sapiently added that he ' might have done a good deal of harm An ordinary person would perhaps have used the word ' wicked instead of *stupid* The bench decided to deal leniently with the prisoner, so he was ordered to pay £5 as damages and a fine of a guinea and costs or to go to prison for a month Why should such special tenderness be shown in a case of wholesale and reckless poisoning of beer?

Feb 25th

## WALES AND WESTERN COUNTIES

(FROM OUR OWN CORRESPONDENTS )

### *Vaccination Fees at Cardiff*

THE Cardiff Board of Guardians has always resented the payment of increased fees to the public vaccinators of the union and at a meeting of the committee of the Association dose of five centigrammes was administered a blood-count on the following day showed rapid regeneration of the red blood cells, and within 48 hours the number of red blood cells per cubic millimetre passed from 2,740,000 to 3,420,000 in one case and in another from 3,800,000 to 5,022.000. This drug, it would seem, therefore, has a great future before it in the various colonies.

### *Public Hygiene and Mortality.*

With reference to the question of the depopulation of France M. Papillon recently read a most striking paper before the Statistical Society of Paris. He commenced by pointing out that in France the statistics of births and deaths were very incomplete. France, continued M. Papillon, enjoys a temperate climate and possesses a soil so fertile as to produce everything that she can require. Yet her birth-rate is the lowest in Europe and her mortality grievously high. This is not due to natural causes, but to the customs of the country. Of a population of 38,000,000 150,000 die annually from tuberculosis, while Great Britain with a population of 41,000,000 only loses 60,000 from the same cause. In every other European country tuberculosis is decreasing, in France it is increasing, because in every other European country alcoholism is decreasing while in France it is on the increase. Here are some figures. Between two censuses the tuberculosis mortality has increased in France by 68 per 100,000 inhabitants. In Germany it has decreased by 109 per 100,000 inhabitants, a difference of 177 per 100,000. This means that nearly 68,000 lives have been lost to France each year by tuberculosis that could have been preserved. Again, there is typhoid fever, a disease which is eminently preventable. The mortality from this disease amounts each year to from 10,000 to 12,000 and these deaths are of young persons just on the threshold of the procreative period of life. In France small-pox kills annually 3000 people, while in Germany the same disease kills one or two. Rabies is unknown in England owing to the strict muzzling and quarantine regulations. The eruptive fevers exact a heavy toll of life in France owing to non-disinfection of houses and personal belongings. These diseases could easily be avoided altogether or at least kept from spreading Another cause of depopulation is syphilis which either brings about sterility or gives rise to a progeny blighted from the birth. If the money value of a middle-aged man be taken at 5000 francs France has to submit to an annual loss of 400,000,000 francs of human capital, to say nothing of dilapidations of human energy caused by an excess of infectious disease. France, together with Germany and England, possesses excellent laws, but they are not carried out because outside the diseases enumerated in statistical tables there is another disease not mentioned in international nomenclature, probably because it is national. It is the electoral disease of drink-shops and public-houses which are not obliged to possess even a municipal licence because producers of alcohol are considered as merchants of the same class as those producing other goods. Dogs are far too lightly taxed, revaccination is only occasionally carried out, and the water-supply is in the hands of an engineer, while at Berlin the chief of the water-supply is a skilled hygienist. With regard to tuberculosis there are laws against insanitary dwellings, but they are not enforced owing to local interests. Cowsheds are not properly supervised, piggeries have no supervision whatever, and private slaughter-houses are still allowed to exist. After 17 years' consideration the two Chambers have just formulated a law with regard to the protection of the public health, but it will come to nothing, for there is no one charged with seeing that its provisions are carried out. If the various prefects are charged with its administration they will consider matters of convenience rather than those of health. In France sanitary powers and responsibilities are scattered abroad amongst three departments—those of the Minister of the Interior, of the Minister of Commerce, and of the Minister of Agriculture. All these administrations should be centralised under one under-secretary with an organisation at his command of sanitary medical officers who should have a free hand. Moral responsibility would thus be increased and statistics of death would no longer be tabulated under the two headings of "cause unknown" and "other causes."

### *The Diagnosis of Real from Apparent Death.*

The Dugaste prize of the Academy of Sciences for 1900 was awarded to Dr. Icard of Marseilles for a method devised by him of diagnosing by means of fluorescine when death has actually taken place. The test depends upon an absolute physiological fact. No absorbable substance can be taken up by all the body tissues except the circulation be in action. Any absorbable substance injected subcutaneously will be absorbed if the circulation persists. If, then, a substance injected into the leg is after a certain lapse of time found in the tissues of the arm it must have been carried thither by the blood-stream and it can therefore be definitely affirmed that at the moment of injection the circulation, or in other words life, was present. Dr. Icard makes use of a solution of fluorescine. So great is the tinctorial power of fluorescine that one gramme will colour 45,000 litres of water. It is not poisonous, caustic, or irritant. Within two minutes after the injection of fluorescine under the skin of a living body the skin and the mucous membranes show an intense colouration and the subject appears to be suffering from acute jaundice. The tissues of the eye are stained a bright green colour, the pupil disappears, and it looks as if a magnificent emerald had been set in the orbit. The tears, the saliva, and the urine are all coloured and one drop of blood or urine added to a glass of water makes it of a bright grass-green tint. Within an hour or two all these symptoms disappear, the fluorescine having been eliminated by the kidneys.

Feb. 25th.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

### *Royal Victoria Hospital, Montreal.*

AT the annual meeting of the governors of this institution held early in January it was announced that extensive additions were to be made to the hospital during the present year, including two new operating theatres, one for the gynæcological department and another for special cases. The annual medical report was submitted and showed that during 1901 2579 patients had been admitted to the hospital, 421 being private ward patients. On Jan. 1st, 1901, there were 194 patients in residence. During the year 2600 were discharged, of whom 1583 recovered, 792 improved, 59 did not improve, 51 were not treated, 115 died, and 173 remained in the hospital at the end of December, 1901. The death-rate for the year has been 4 42 per cent., or, if 23 who died within 48 hours of admission are deducted, the death-rate would be 3 54 per cent. In the out patient department the total number treated was 3601. The income of the hospital for the year amounted to $130,738 40, while the ordinary expenditure amounted to $112,280 20, leaving a balance or $18,458·20 which is being applied towards the cost of a new power house and isolation pavilion.

### *Quarantine on the Pacific Coast.*

With the permission of Dr. Montizambert, the Director-General of Public Health, quarantine arrangements on the Pacific Coast have been made affecting the Empress line of steamers plying between Vancouver and the Far East. Formerly these steamers were compelled to go into quarantine at the Williams Head Station and remain there for four or five hours, often at great inconvenience to the passengers, even when there was no case of contagious disease on board. Under the new order the steamers will be obliged to touch at quarantine only when any contagious disease has developed on the voyage. Better connexions will thus be established for the overland trains from Vancouver.

### *Reforming the Ontario Medical Council.*

A Bill is now before the Ontario Legislature which seeks to make radical changes in the constitution of the Ontario Medical Council, the governing body of the College of Physicians and Surgeons of the province. As at present constituted, the council consists of 30 members, five of whom represent homœopathic practitioners and eight are non-elected appointees from the medical colleges connected with four of the universities in the province—viz., Toronto, Queen's, Trinity, and the Western at London. The other 17 members are elected by the regular profession throughout the province. There are only about 40 homœopathic practitioners in the province, while each elective representative of the regular profession has a constituency of 250, hence the present constitution of the council is considered to be very unfair to the regular profession. The proposed amendment to the Medical Act seeks to abolish this special provision for the homœopathists and the College representation on the heartburning in Edinburgh over the question of the examination of pathological products for the public health authorities. For some time past the work has been done in the laboratory of the Royal College of Physicians of Edinburgh at a small charge for each specimen examined. The trustees of the Usher Institute of Public Health which is attached to the University of Edinburgh have meanwhile approached the Public Health Committee of the town council with a view to having the bacteriological examination of products from suspected cases of infectious disease transferred to that institute. The Royal College of Physicians, supported by the Royal College of Surgeons, very naturally objected to this move on the part of the University and called a meeting of the profession in Edinburgh to consider the matter. The meeting was duly held, but, as so often happens, the profession as a whole showed no burning interest in the question. A resolution was, however, carried to the effect that the profession in Edinburgh was entirely satisfied with the manner in which the work had been done at the laboratory of the Royal College of Physicians. The matter thereafter came up before the Public Health Committee of the town council. That body very wisely determined that no arrangement could be regarded as final and satisfactory which did not provide for the class of work referred to being undertaken directly by the public health authorities, and decided that as the present arrangement with the Royal College of Physicians of Edinburgh was a temporary one it should not be disturbed at present.

Feb. 24th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Small-pox in Dublin.*

No fresh case of small-pox has appeared in Dublin, and the isolation hospital at Findlas contains only three patients. The warning has probably been useful, for revaccination is being largely practised in mercantile establishments and in colleges. It is satisfactory to note Dr. E. J. McWeeney's statement that the anti-vaccinationist is almost entirely unknown in Ireland.

### *A Case of Poisoning by Belladonna.*

A case came before Master Courtenay and a jury on Feb. 21st in which a young girl named Jane Crinion brought an action for damages against T. W. Britain, a pharmaceutical chemist, carrying on business in Drogheda, for negligence alleged to have been caused in preparing medicine. It appeared that two drachms of extract of belladonna were given to the plaintiff in mistake for confection of senna. A few moments after swallowing the dose the girl fell to the ground, and it was then discovered that she had taken about 120 grains of extract of belladonna. An emetic was administered and the stomach-pump was made use of as soon as possible, but it was many hours before she recovered consciousness. She complained that her eyesight and heart were still affected, although it is now more than seven months since the act of alleged negligence occurred. Damages were fixed by consent at £200.

### *Dublin Sanitary Association.*

The annual general meeting of the Dublin Sanitary Association was held on Feb. 20th at Leinster House, Kildare-street. Sir Christopher Nixon, President of the Royal College of Physicians of Ireland, in moving the adoption of the report, alluded to what he stigmatised as the absurd position taken by Kingstown, Blackrock, and Dalkey in connexion with the compulsory notification of infectious diseases. He considered that it was quite time that the law with regard to this matter should be assimilated to that which prevails in England. He would also advocate the extension of the law generally as it exists in England and Scotland, especially as to the appointment of officers of health for certain areas who could give their entire time to the work. He made an important suggestion in reference to the almost complete absence in Dublin of accommodation for patients suffering from consumption who were not fit subjects for a general hospital. The authorities of the Mater Misericordiæ Hospital had recently provided a convalescent home in Santry and had acquired there from 110 to 120 acres of land—ground enough for the erection of suitable cottage hospitals. He thought it possible that this ground might be given over for the erection of sanatoriums if it was required for that meritorious purpose. After the adoption of the report Dr. Charles F. Moore, the learned president of the association, delivered a very interesting address dealing with the necessity for compulsory revaccination and with other matters of medical and public importance.

### *The Belfast Maternity Hospital.*

At the annual meeting of the supporters of this charity, held on Feb. 20th, it was reported that during the year 304 patients were treated and 271 children were born (141 males and 130 females), with only one death. 582 patients had been treated in the extern department.

### *The Small-pox Epidemic.*

So far no cases of small-pox have occurred in Ulster, with the exception of one case reported from Kilrea, where a young woman, a workmistress in the National School in Kilrea, county Derry, developed the disease at the end of last week. She was removed to Ballymoney Hospital. How she contracted the disease remains a mystery. Some think that it was conveyed through letters from Glasgow; others that it was through a visit from a friend from that city. The Limavady Board of Guardians has had before it the question of purchasing the iron hospital at Magilligan, formerly used as an intercepting hospital, to be used if required as a small-pox hospital in the workhouse grounds.

### *Death of Mr. S. A. K. Strahan, M.D. R.U.I., L.R.C.P. Edin.*

The death in London on Feb. 21st of Dr. Strahan is announced. He graduated as M.D. of the Royal University of Ireland in 1879 and devoted himself to the study of mental disease.

### *The Cork School of Medicine and the Examining Board of the Royal University of Ireland.*

For many years the gravest dissatisfaction has existed in the Cork School of Medicine owing to the manner in which the board of examiners of the Royal University of Ireland is constituted. Though a large number of medical students from Cork have graduated at that University, yet since its foundation not even once has an examiner in medicine or surgery been appointed from Cork,, neither for nearly 20 years has the Cork school been represented by an examiner in midwifery. The medical students in Cork have come to realise the situation and they present themselves for the Royal examinations in fewer and fewer numbers every year. The council of Queen's College, Cork, and the Cork Medical and Surgical Society have addressed communications to the Senate of the Royal University on the subject, and it is to be hoped that their remonstrances will have an effect, as it seems a pity that so many students from Cork should consider it desirable to incur the expense of crossing over to Scotland for their qualifications.

Feb. 25th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Arrhenal.*

AT a meeting of the Academy of Medicine held on Feb. 11th M. Armand Gautier, to whom is due the introduction into therapeutics of that remarkable drug cacodylate of sodium, brought forward a new arsenical compound closely allied to the cacodylate—namely, di-sodic methyl arsenate. This substance M. Gautier has called for short "arrhenal," arrhen being an early name for arsenic. Arrhenal is no more poisonous than is cacodylate and possesses the same therapeutic properties, only it acts with greater vigour. It has without giving rise to any unpleasant consequences, whereas the great advantage of *being administrable* by the mouth cacodylate decomposes in the alimentary canal, giving off the toxic oxide of cacodyle, so that it can only be administered by hypodermic injection. Arrhenal is a powerful tonic and acts admirably in all cachectic states, even in tubercle and in cancer if given at an early date. M. Gautier has used it specially in malarial cachexia and found it superior to quinine. M. Billet has made trials of it in the military hospital at Constantine. Patients suffering from a severe form of quotidian fever showed a normal temperature on the day after taking it and some of them remained for three months without a relapse. Moreover, when the blood of such patients was examined under the microscope the process of phagocytosis of the malarial hæmatozoa could be watched. If one

# THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

A SPECIAL session of the General Medical Council was opened on Tuesday last, Feb. 25th. The President of the Council, Sir William Turner, K.C.B., presided over a full meeting of the Council, including the three new members, Dr. D. W. Finlay, Dr. J. Y. Mackay, and Mr. George Jackson.

The session was summoned, it will be remembered, to consider the report of a committee appointed to inquire into the differences existing between certain licensing bodies and the Council regarding the courses and conditions of medical study. But when the Council found itself meeting on the eve of the second reading of the Midwives Bill it very rightly decided to consider this measure before proceeding to the special business. As a result the Council came to the conclusion to adhere to its previous resolutions in regard to the Midwives Registration Bill. and decided, as we foreshadowed in our leading article last week, that the measure read in the House of Commons for the second time on Feb 26th was not in accordance with its resolutions. The Council therefore requested Sir John Batty Tuke, in the event of the Bill being read a second time, to communicate its views to the Grand Committee on Law. As all our readers know, the Bill was read for the second time on Wednesday last without a division, in spite of the efforts of Sir John Batty Tuke, who moved its rejection, of Sir Walter Foster, Mr. Ambrose, Mr. T. P. O'Connor, and others.

Dr. D. C. McVail's committee then presented its report, to consider which the special session had been summoned. The interesting observations and conclusions of this committee, which we reproduce in full, should be studied by all our readers. Certain points in medical education are summarised in a clear and comprehensive manner in the report. Two opinions relating to the subject from the counsel to the General Medical Council, Mr. Muir Mackenzie, were entered upon the minutes and will be found in our columns. In both Mr. Muir Mackenzie advises the Council that it has jurisdiction over the different courses of study to be gone through by candidates for registration. Dr. McVail then urged the adoption of the report by the Council, upon which would follow recourse to the Privy Council if the licensing bodies in question continued to differ from the view of the General Medical Council. Dr. Norman Moore, after pointing out that he and Mr. Bryant had sat on the committee not as representatives of the English Royal Colleges but as members of the General Medical Council, advocated an inquiry by the Council into the particular courses and institutions considered to be at fault before the Privy Council was approached.

The rest of the debate on the medical curriculum foreshadowed that when a division was taken the report of the Special Committee would be adopted; but at the same time the gravity of referring the matter to the Privy Council on the ground of the "insufficiency" of the Royal Colleges was fully recognised. In the end the Council voted by 17 to 4 to adopt the report "as far as page 53"—i.e., as far as Dr. McVail's motion had reference. A motion by Dr. MacAlister, seconded by Dr. McVail, was in the end unanimously agreed to, which put off appeal to the Privy Council, by requiring the Conjoint Examining Board in England to furnish the General Medical Council with certain information concerning the examinations of the Board in the preliminary subjects of medical study.

The special session concluded its work on Wednesday afternoon, Feb. 26th.

## SPECIAL SESSION.

### TUESDAY, FEB. 25TH.

The special session of the Council was opened in the Council Chamber, Oxford-street, Sir WILLIAM TURNER, K.C.B., President of the Council, occupying the chair.

### *Introduction of New Members.*

The following new members were introduced—namely, Dr. David White Finlay, representative of the University of Aberdeen; Dr. John Yule Mackay, representative of the University of St. Andrews; and Mr. George Jackson, F.R.C.S., one of the recently elected Direct Representatives for England. Dr. Finlay and Dr. Mackay were introduced by Sir William Gairdner and Mr. Jackson by Mr. George Brown.

### THE PRESIDENT'S ADDRESS.

The PRESIDENT said: Since the last meeting of the Council several changes have taken place in its *personnel.* As a result of the election of two Direct Representatives of the profession in England the seat for so many years occupied by Dr. Glover, whose impending retirement on account of health I intimated in November, has been filled by the election of Mr. George Jackson, and Mr. George Brown has again been chosen. Dr. William Bruce has also been re-elected by the registered practitioners resident in Scotland. Dr. Pettigrew has retired from the representation of his University. With one exception he had occupied a seat at our Council Board for a greater length of time than any other member. Originally chosen in 1877 to represent the Universities of Glasgow and St. Andrews, and 10 years afterwards as the representative of St. Andrews, when the Act of 1886 gave to the latter University the power to elect its own member, he has been in continuous occupation of his seat for 25 years. Dr. Pettigrew took a strong personal interest in the work of the Council. We shall miss his genial presence, and the experience which he gained during so many years in the management of our affairs. Dr. John Yule Mackay, Principal of University College, Dundee, which is now a constituent part of the University of St. Andrews, has been appointed his successor. Dr. Robert William Reid, who for five years represented the University of Aberdeen, and who during his period of office took an active interest in the subjects which came under the consideration of the Council, more especially in the work of the Education Committee, has been succeeded by Dr. David White Finlay, professor of medicine in that university. The Council welcome to their board the new and the re-elected members. The Council will recollect that on Dec. 3rd of last year it was resolved to appoint a committee to report on the differences that exist between certain licensing bodies on the one hand and the General Medical Council on the other regarding the courses and conditions of study and the recognition of the institutions and schools in which the required courses may be taken, and that a special meeting of the Council to consider the report should take place on the fourth Tuesday in February of this year. This is the reason why we have been called together at this unusual period. The committee's report has been for some days in your hands, and members of Council, in view of the momentous issues which have been raised in it, will, I feel sure, have given it their close attention. It is, I have no doubt, in the knowledge of all of you that a Midwives Bill has been introduced into the House of Commons during the present session and is to be read a second time during this week. I instructed our Registrar to obtain copies of the Bill as soon as it was printed, and to forward one to each Member of Council. You will observe from the programme of business that a copy of the Bill has been sent officially by the Lord President of the Privy Council for our information. As the consideration of a Midwives Bill formed no part of the business specified in the resolution of December last by which this meeting was fixed it will be necessary, in accordance with Standing Order 1 (3), should the Council desire to discuss this Bill and to offer an opinion on it, that a motion to this effect should be agreed to by the Council before any discussion can take place. I shall therefore put to the council and to provide that all the members should be elected by the whole profession throughout the province. The Bill is now before a special committee of the House on which all the medical and legal members are serving.

### *The South-Western Medical Association of Manitoba.*

Two or three months ago the members of the profession in the south-west part of the province of Manitoba met and organised themselves into an association with the above title. Out of 70 practitioners in the district it speaks well for the medical body when it is stated that 67 of these immediately signed the roll, and there are good prospects of the remaining three doing likewise in the near future. The objects of this organisation are set forth as follows in a circular letter issued to the profession in Manitoba. Insurance companies will have to pay $5 for an examination, lodges with no insurance $2, and lodges with insurance $3 Lodge practice is discountenanced. A provisional tariff of fees has been fixed and all will endeavour to adhere to it as closely as possible. The organisation has also decided that it will be better in the interests of the profession if all render their accounts at least quarterly. A strong effort will be made to bring the whole profession in the province of Manitoba into the organisation.

### *Ontario Death-roll in 1901.*

A statement recently issued by the Board of Health of the province gives the details regarding the deaths from contagious diseases occurring in 1901, 90 per cent. of the population reporting. The total deaths from all causes number 25,736, or 13·1 per 1000 as compared with 25,382 occurring in 1900 Tuberculosis caused more deaths than any other contagious disease—viz., 2286. This was not so large as in 1900, when the total was 2360. June was the healthiest month with a total of 1608 deaths; March showed the heaviest death-roll with 2525 deaths. Scarlet fever claimed 209; measles, 120; diphtheria, 512; whooping-cough, 112; and typhoid fever, 345. The mortality from typhoid fever in 1900 was 550.

### *Small-pox in Ontario.*

It begins to look as if Ontario was in for a big epidemic of small-pox. Although the disease is pretty well under control in the unorganised districts amongst lumber camps, mining and construction camps, &c., where some 60 physicians have recently been appointed by the managers, the older and better settled sections of the province are now being attacked; and the last statement issued from the Board of Health shows that there were 629 cases in the province in the month of January. These patients are scattered over 28 counties with 87 centres for infection. Ontario is pretty bad, but many of the States of the American Union are much worse.

Toronto, Feb. 4th.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

### *Leprosy Bill for America.*

SENATOR PLATT of New York has introduced into the National Legislature a Bill to Prevent the Spread of Leprosy, some of the provisions of which are as follows:—The appointment of a leprosy commissioner to reside at New York or San Francisco. with a yearly salary of $5000 (£1000); the setting aside of a mile square for a national leper home, the site to be chosen by a leprosy board; the appropriation of $50,000 (£10,000) to erect suitable buildings for the habitation of lepers in the United States, not including Hawaii, Porto Rico, Cuba, or the Philippines; the transportation of lepers who are unable to care for themselves to the national leper home; the injunction of steamship companies or individual vessels or railroads from bringing to the United States any leper or from accepting any immigrant from any of the countries known to be leprous without a special certificate; the strict supervision for seven years of immigrants of leprous families, though they themselves be free from the disease; the deportation of any leper who, despite all precautions, manages to enter the United States; no discrimination to be made on behalf of Americans who contract the disease in a foreign country; the Marine Hospital Service of the Treasury Department to have full charge of the National Leper Home. There are probably more cases of leprosy in the United States than is generally believed, and the enactment of such measures as the foregoing would not only prevent the spread of the disease (that is taking the view of the majority as to its contagiousness) but would impart a feeling of confidence among the general public.

### *Reforms in the New York City Hospitals.*

Some months ago the revised charter of the city of New York provided that the charity hospitals, Bellevue, Harlem, Gouveneur, and Fordham should pass from the control of the Charities Department—under which management they have been for many years—to a board of trustees consisting of seven members. With the change of the city administration the new board appointed by Mayor Low has entered upon its duties The city institutions will be subjected to thorough reforms and the existing methods of management will be very considerably altered. Bellevue Hospital, by far the largest and most important of these institutions, will naturally receive the lion's share of the new board's attention. The insane pavilion of Bellevue will be first taken in hand and it will be converted into what will practically be a temporary insane asylum. The alcoholic ward, so far as management is concerned, will be swept and garnished, and the nurses and attendants throughout the establishment will be paid fair wages. The statement is also made that a large appropriation of money will shortly be asked for, and that if the request be granted Bellevue will be rebuilt. It seems that the time is really now approaching when New York will have charity hospitals worthy of her position as the most important and the richest city of the United States.

### *Osteopathy in New York State.*

This method of treating disease has become vastly popular in many parts of the United States, thus once more showing the gullibility of the human race. In some States the practice of osteopathy has been placed on a par with medical practice and to its professors have been granted all privileges and powers accorded to the men who hold a degree in medicine. Aided by the backing of influential persons in New York State, the osteopathic fraternity have for some considerable time been making determined and strenuous efforts to be placed upon an equal footing with graduates in medicine and surgery. A Bill to this effect was introduced into the New York State Legislature in the present session The osteopaths set forth their qualifications to be given the right to treat disease of all kinds and to sign death certificates. They stated that everything is taught in osteopathic colleges that all medical colleges teach except materia medica. Naturally the medical profession opposed the passage of such a Bill with all its might and showed up many of the fallacies of osteopathy. For instance, it was pointed out that while the osteopathic colleges pretended to teach all branches of medical science except materia medica, the time devoted to this teaching made of the whole affair a complete farce. The whole osteopathic course in its prominent colleges is only two years, and the time given to the teaching of such important subjects as anatomy and physiology is so short as to be utterly absurd. It is therefore gratifying to be able to announce that the Bill to place osteopathy upon the same plane as regular medicine has again failed to pass in New York State.

Feb 18th.

---

VACCINATION STATISTICS.—At the meeting of the Axbridge Board of Guardians held on Feb. 18th it was reported that during the half-year ended June, 1901, the births of 502 children were registered, 272 successful vaccinations were performed 85 certificates of conscientious objection to vaccination were granted, and 43 children died unvaccinated. In Weston-super-Mare, the figures for which are included in the above returns, 232 births were registered, and only 89 children were successfully vaccinated.

TORBAY HOSPITAL, TORQUAY.—The annual meeting of the governors of this hospital was held on Feb 20th. The medical report stated that 401 in-patients had been admitted during 1901, compared with 339 in the preceding year. 706 out-patients had been treated, exclusive of 628 ophthalmic cases In the provident dispensary department 125 new cases had been admitted. The financial statement showed that the total expenditure amounted to £2325, and that there was an unfavourable balance of £57. The report added that at the closing of the Syracusa Convalescent Home the committee had presented the hospital with the Roentgen ray apparatus.

referred to were under the control of medical practitioners and therefore he submitted that there was no parallel to be drawn with the provisions of this Bill. Under this Bill the midwives were independent of medical practitioners.

Sir John Williams explained that the cases were only visited by medical practitioners when difficulty arose.

Dr. Norman Moore said that his view was that if it were thought that this Bill would improve the present state of things and not make it worse they should endeavour to amend the Bill.

Dr. Atthill said that he had always been an advocate for the education of midwives, but he regarded this Bill as a positive evil.

Dr. Heron Watson said that it was a bad Bill root and branch and ought to be opposed.

Sir William Gairdner said that the conferences with the promoters of this legislation which had taken place had left him with the impression that their desire was to be in accord with the wishes of this Council.

The President intimated that he had received a letter from one of the most active promoters of the Bill. In this letter the writer said that he believed the Government would agree to the Bill being read a second time on the understanding that all necessary amendments would be made in committee and he could have no doubt that they would seek to obtain the views of the General Medical Council at that stage. The writer continued: "I sincerely hope they will and that those views may receive full and ample consideration at their hands."

Mr. Horsley thought that the President of the Privy Council had gone back on his statement to the deputation of supporters of the Bill when he told them that they must agree with this Council.

Sir Christopher Nixon submitted that the Council should not take up a completely *non-possumus* attitude in this matter, but should discuss the merits of the Bill and try to have the provisions altered according to its wishes.

Dr. McVail thought that they should either pass the matter over altogether or indicate how the Bill should be altered.

It was agreed to insert at the end of the third clause of the motion the words "in its present form."

Thus amended the motion was put to the Council and carried *nemine contradicente.*

It was further agreed that in the event of the Bill being read a second time and referred to the Grand Committee on Law Sir John Batty Tuke be requested to communicate the resolutions of the Council on the subject to that committee.

### *The Medical Curriculum—The Dispute between the Council and the English Royal Colleges.*

The Council proceeded to the consideration of a report on the curriculum by the special committee appointed last December "to prepare a report on the differences that exist between certain licensing bodies on the one hand and the General Medical Council on the other, regarding the courses and conditions of study and the recognition of the institutions and schools in which the required courses may be taken; and that the report be considered by the Medical Council at a special meeting, when the Council will decide what action, if any, shall be taken, and in particular whether the circumstances are such as to require action to be taken under Section XX. of the Act of 1858." This special committee consisted of Dr. McVail (chairman), the President (*ex-officio*), Dr. Norman Moore, Mr. Bryant, Mr. Young, Sir Hector Cameron, Sir William Thomson, and Mr. Ball.

Dr. McVail moved that the report should be received and entered on the minutes.

Exception was taken to several parts of the document, and especially to a "minority" report at the end of it. It was claimed that the latter ought to be signed by the minority who asked it to be presented to the Council. Dr. Norman Moore admitted that he and Mr. Bryant, the representatives respectively of the Royal College of Physicians of London and the Royal College of Surgeons of England, were the minority in question, and said that there was no objection whatever on their part to put their names to the report. Among other corrections agreed to were the deletion of words relating to the University of Durham and the insertion of words to secure accuracy and to give prominence to the fact that the Royal College of Physicians of London is the only individual medical corporation able to grant a complete qualification in medicine and surgery. The report as amended was then put on the minutes. The following (which excludes matter contained in no fewer than 42 printed octavo pages) formed the most interesting portion of it, and as far as the end of "conclusions by the committee" (pages 43 to 53) it was read by Dr. McVail:—

#### *Summary of Narrative.*

The principal events in the foregoing narrative may be briefly summarised as follows:—

In June, 1890.—Adoption of five years' course after registration; physics, chemistry, and biology to constitute the first year. These to be studied in universities, medical schools, or in teaching institutions that are recognised by the licensing bodies.

In May, 1893.—The Medical Council codified its resolutions into requirements and recommendations, the former to be enforced, if necessary, by action taken under Clause XX. of the Medical Act, 1858.

December, 1894.—The Council by resolution authorised chemistry, physics, and biology to be taken before registration at teaching institutions recognised by the licensing bodies, but a full five years of curriculum after registration was still to be enforced. The licensing bodies were requested to send annually lists of the institutions so recognised—after inspection. (So far the Medical Council did not assert a right of approval.)

December, 1898.—A letter read from the Royal College of Surgeons of Ireland calling attention to the large number of teaching institutions recognised by the English Conjoint Board—many of them grammar schools.

June, 1899.—The Medical Council decides that the scientific institutions (the term "teaching institution" disappears) at which study in chemistry, physics, and biology shall quality for registration in the Students' Register must not only have been recognised by one or more of the licensing bodies, but must also have been approved by the Council.

December, 1899.—Refusal of English Royal Colleges to recognise the right of approval as belonging to the Council, or that the Medical Acts gave the Council any authority to impose conditions regarding the registration of medical students.

December, 1900.—Memoranda, counsel's opinions, &c., considered, and Council decides to adhere to requirements, and in effect precludes the registrars from registering students of unapproved institutions, but invests the Students' Registration Committee with powers to deal for the present with such cases.

June, 1901.—The English Royal Colleges intimate to the Council that they no longer require candidates for their diplomas to be registered in the Students' Register.

December, 1901.—The English Royal Colleges in their latest regulations require their candidates to have passed a preliminary examination that is recognised by the Colleges—not, as heretofore, a preliminary examination recognised by the Medical Council. Up to the present the list of preliminary examinations of the Colleges is identical with that of the Medical Council.

The Council appointed the Committee engaged in the present report, and decided to hold a special meeting to consider it.

#### *Observations by Committee.*

From the foregoing narrative of events it will be seen that from 1890 to 1894 one matter was in dispute between the Conjoint Board of England and the Medical Council, and that since the end of 1898 the variance has been on quite another question. In the former period the Colleges desired that recognition should be given to the study of the three science subjects prior to registration, and after a four years' struggle the Medical Council yielded. In the latter period the dispute has been about the institutions to be recognised at which the three preliminary science subjects might be studied. The Colleges, between 1894 and 1898, had been according recognition to a large number of institutions, some of which had been inspected by the Colleges whilst others had been inspected by the Science and Art Department only, and when quite suddenly the attention of the Medical Council was called to this circumstance it began to remonstrate with the Colleges, at first mildly, but these bodies remaining obdurate, the Council passed resolutions gradually more and more stringent, until finally it in effect refused to register students entering at institutions which it itself had not approved. As to the merits of the institutions as places of study for the first year of the curriculum, the Colleges hold that in all of them the teaching is adequate, but in this opinion the Council has not concurred. Quite clearly it was the intention of the Council, when it decreed the five years' professional course in 1890, that physics and biology should be taught as to scope and standard just as chemistry had been taught prior to 1890. Chemistry had a place in the old curriculum beside anatomy and physiology and other branches of medical science. A course during a full session of systematic chemistry had been imposed, just as a systematic course of a full session in anatomy was required, and instruction in practical chemistry of a duration of at least two months and a half was demanded. In every respect chemistry had been an integral subject of the medical curriculum to be taught in a university, a recognised medical school, or in a college of science. When physics and biology were introduced into the curriculum and the period of the curriculum was extended to five years the Medical Council intended that these subjects should receive, in relation to the time to be given to them respectively, place and consideration not inferior to those accorded to chemistry or any other subject of medical study. The Council did not contemplate these two new subjects as being taught together with ordinary school subjects in day-schools, and still less that the teaching of chemistry should be reduced with them to an ordinary school level. The Council had permitted the introduction of the words other "teaching institutions" without perhaps apprehending the direction and the length to which this concession would lead. When the Council at the end of 1898 had awakened to some appreciation of the results of its concession in 1890, it began to take steps to arrest and correct the evil. But all such efforts the London Colleges have opposed most strenuously, until the rupture is complete, and the Colleges will confer their diplomas without regard to the Medical Council's directions and resolutions. In 1899 and in 1900 the Council has, by large majorities, repeatedly in its resolutions expressed its opinion that under the widespread recognition of institutions by the London Colleges the study of the three science subjects is not sufficiently safeguarded as to its scope and standard, and

Council the two following questions: 1. Shall the Council consider the Midwives Bill at this special meeting? 2. Shall the Council consider the Midwives Bill before proceeding to the special business for which it is summoned?

These questions were put from the chair and in each case the answer of the Council was in the affirmative.

### *The Midwives Bill.*

Mr. HORSLEY moved that the Council should proceed to consider the letter of the Lord President of the Privy Council transmitting to the Council for the information of members a copy of the Midwives Bill as introduced in the House of Commons during the present session.

Dr. ATTHILL seconded this motion, saying that it would strengthen the hands of the members of the House of Commons who opposed the Bill if this Council gave its opinion about the measure.

The motion was agreed to.

Dr. ATTHILL moved :—

(1) That the Council adheres to the resolutions in regard to legislation for midwives which it adopted at a special meeting held in April, 1898, and communicated at his request to the Lord President of the Privy Council; (2) that the Council is of opinion that in important respects the provisions of the Midwives Bill, 1902, are at variance with the principles thus adopted by the Council, and do not embody the safeguards for the protection of the poor which it regards as essential; (3) that accordingly the Council is of opinion that the Midwives Bill, 1902, now before Parliament, ought not to pass into law; (4) that the foregoing resolutions be communicated forthwith to the Lord President of the Privy Council.

The terms of the resolutions of April, 1898, are as follows, viz. :—

1. That the Council adheres to its previous resolutions affirming that it is desirable that measures should be taken to protect lying-in women of the poorer classes from the grave risk which they now incur from the unregulated practice of midwives, many of whom are ignorant and unskilful, and most of whom pursue their calling without due medical supervision.

2. That to this end it is desirable that every woman who, not being a registered medical practitioner, engages for gain in practice as a midwife should be subjected to legal regulation and control.

3. That any measure which proposes merely to protect the title of "midwife," however defined, and does not make illegal and penal the unlicensed practice of midwifery for gain, cannot be regarded as offering a sufficient safeguard in the interest of the public health.

4. That some central body should be established by Parliament whose functions should include the framing of the conditions under which midwives may be licensed and of the regulations under which alone they shall be allowed to practise.

5. That the conditions and regulations so framed should be subject to the approval of the General Medical Council, and if and when so approved should be issued to the local sanitary authorities by the State department which is concerned with the public health.

6. That provision should be made by Parliament for reimbursing the Council for any expenditure which it may have to incur in performing the duty hereinbefore referred to.

7. That every woman, before beginning to practise as a midwife in any district, should be required to take out a licence, to be granted by the local sanitary authority of the district under the prescribed conditions and regulations. That such licence should be subject to annual renewal, and should be revocable at any time in case the holder is proved to have infringed any of the prescribed regulations.

8. That any unlicensed woman, whether calling herself a midwife or not, who, not being registered under the Medical Acts practises as a midwife for gain in any district, should be made liable to a substantial penalty.

9. That the conditions under which licences are granted should include the production of satisfactory evidence of character and of training and experience in the conduct of natural labour and in the after-care of lying-in women and new-born infants.

10. That the regulations under which licensed midwives are required to practise should include provisions securing that the midwife shall immediately seek qualified medical assistance in every case which presents symptoms of difficulty, abnormality, danger, or disease on the part of the mother or of the new born infant.

11. That in so far as the Bill submitted to the Council is not in accordance with the general principles above laid down, the Council do not regard it as offering a solution of the question under consideration and would earnestly deprecate its passing into law in its present form.

Dr. ATTHILL said that he considered it essential that the Council should adhere strictly to the opinions it had clearly announced in these resolutions. It was inadvisable that they should discuss the provisions of the Bill now before Parliament. For himself he considered it the most objectionable Bill on the subject that had come before the House of Commons. In 1898 the Privy Council sent the Bill of that year to this Council and asked the opinion of the Council upon it. On the present occasion the opinion of the Council was not asked; the Bill was merely sent for the information of the Council. There were two points in particular on which the Council had always insisted: that no Bill should pass in which there was not a provision that in cases of difficulty the midwife should be compelled to call in the aid of a registered medical practitioner, and that there should be an annual fee for re-registration in order that midwives might be kept under supervision. These were the two chief details and if they were omitted from any Bill he believed that incalculable damage would be done.

Dr. P. HERON WATSON seconded the motion.

Mr. GEORGE BROWN said that he entirely approved of the proposed action. He thought it highly desirable that the Lord President of the Council should understand that this Bill was a departure from the measure of which the Council approved to a certain extent. All the safeguards which the Council had wished to see introduced had been dropped, and, indeed, the Bill was one which the Government should not aid in any way. The Bill professed to be framed in order to protect the poor against the practice of ignorant and inefficient midwives, but as a matter of fact it did nothing of the kind; it simply protected the title of "midwife." Should the Bill become law the old Sairey Gamp, the discredited village midwife, would be allowed to practise without let or hindrance. That fact of itself ought to be enough to make the Legislature reject the measure. Moreover, there was no penalty for those who, registered under the Act, failed to call in medical aid in dangerous cases. If the Bill were to meet its avowed purpose it must provide for efficient nursing during the lying-in period. Indeed, the Bill was totally inadequate and was condemned by the medical profession.

Dr. MACALISTER said that it was desirable to point out that the present Bill was at variance with each of the articles of faith set forth in the resolutions of April, 1898. It did not propose to regulate the practice of all women who practised as midwives. It only proposed to make regulations for those who took out certificates and called themselves midwives—a very small proportion of the total number. This comment also met the second resolution. As for the third resolution the Bill proposed merely to protect the title of midwife and did not contain the safeguard which the Council considered essential. It was quite true that the Bill proposed to establish a midwives' board, and that board would deal only with the *élite* of the profession who held certificates. It did not draw up regulations under which alone midwives should be allowed to practise. For the first time in a measure of this kind the approval of this Council was not required. All that was required was that the Privy Council should approve the rules after consultation with this Council. The consultation might be merely formal and any recommendations made by this Council might be entirely disregarded. With regard to the sixth resolution there was no proposal for reimbursing this Council for any expenditure it might incur in this connexion. Under the Bill a woman could notify if she pleased, not to the sanitary authority, but to the county or district council, and she need not apply annually for her licence. Therefore an important safeguard was lost. As to resolution No. 8 a penalty appeared in an incomplete form in a previous Bill, but it had been entirely left out of this measure. As to the ninth resolution the only persons who had to produce any evidence of character were those who applied to be licensed on the ground of their having been in practice for two years prior to the passing of the Act. All other applicants for certificates had no character conditions to satisfy. As to the tenth resolution there was no such provision in the Bill and none was likely to be introduced in rules framed by a midwives' board constituted in the manner proposed. For these reasons he desired to support the motion.

On the suggestion of Sir HECTOR CAMERON it was agreed to delete from the motion the qualifying words "in important respects"

Sir JOHN WILLIAMS said that as this was a Bill for the improvement of midwives it was well to consider what was the effect of the present system of educating and registering them. He had made some inquiries with regard to midwives connected with the out-patient departments of hospitals in London and he found that whereas the mortality in childbirth throughout the country was one in 200, in this particular practice it was only one in 1000. Any measure which would help to bring about such a result as that was surely deserving of consideration. He based this statement on the report of the Registrar-General.

Dr. MCVAIL asked whether the Registrar-General's report stated how much of this mortality occurred in cases attended by qualified medical practitioners and how much in cases attended only by midwives.

Sir JOHN WILLIAMS said that he could not answer that question.

Mr. HORSLEY said that he understood that the midwives subjects at institutions which have been approved by the Medical Council; nevertheless, this Conjoint Board admits candidates to its second and subsequent professional examinations when such candidates produce evidence that they have passed the first professional examination of the Conjoint Board of England, and that the regulations of the Scottish Conjoint Board do not require in such cases evidence that the courses of study in chemistry, physics, and biology undergone by such candidates have been so undergone at scientific institutions which have been approved by the Medical Council.

IV. The Society of Apothecaries of London, although requiring evidence that candidates who present themselves at its first professional examination, which includes the subjects of chemistry, physics, and biology, shall have been registered in the Students' Register, and thus must have taken the courses of study in these subjects at institutions which have been approved by the Medical Council; nevertheless this Board admits candidates to Part II. of its primary professional examination when such candidates produce evidence that they have passed the first professional examination of the Conjoint Board of England, and that the regulations of the Society of Apothecaries do not require in such cases evidence that the courses of study in chemistry, physics, and biology undergone by such candidates have been so undergone at scientific institutions which have been approved by the Medical Council.

V. The University of Oxford prescribes practically no curriculum of study to be undergone by candidates previous to their admission to the professional examinations conducted by that university for its degrees in medicine, nor does it require candidates to have been engaged in medical study for any definite minimum terms of years, and it does not require evidence of registration in the Students' Register. It asks only that candidates for its second and final examinations for the M.B. degree "must present certificates of instruction in infectious diseases and mental diseases, and of attendance in labours and of proficiency in the practice of vaccination."

VI. The University of London admits candidates to its preliminary scientific examination, which is one of the examinations for the medical degree, altogether irrespective of evidence of study in these subjects at any scientific or teaching institutions. As regards the remaining subjects of the medical curriculum the University of London requires evidence only that five of 11 subjects which it enumerates shall have been taken in universities, schools of medicine, and hospitals approved by it. The university does not require evidence of registration in the Students' Register, but it does require that candidates for its medical degrees shall have been engaged for five years in medical study subsequently to their having passed their matriculation examination, and four years subsequently to having passed the preliminary scientific examination.

### *Recommendations by the Committee.*

The committee recommends the Medical Council to adopt the following resolutions:—

I. That many courses of study in the subjects of physics, chemistry, and biology are accepted by the Conjoint Board (constituted in terms of Section III., Sub-section (i.), paragraph (*b*), of the Medical Act of 1886) of the Royal College of Physicians of London and the Royal College of Surgeons of England as parts of the curriculum to be gone through in order to obtain the respective qualifications of these bodies, which qualifications are mentioned in Schedule (A) of the Medical Act, 1858, and admit to the Medical Register; and that these courses of study of chemistry, physics, and biology, pursued at institutions which are not universities or recognised medical schools or scientific institutions approved by the Medical Council, do therefore not secure that the persons who pursue such courses of study, and who afterwards obtain the qualifications of the Royal College of Physicians of London and the Royal College of Surgeons of England, possess the requisite knowledge and skill for the efficient practice of their profession.

II. That many courses of study in the subjects of physics, chemistry, and biology are accepted by the Conjoint Board (constituted in terms of Section III., Sub-section (i.), paragraph (*b*) of the Medical Act of 1886) of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, under No. 10 of the regulations of that board as parts of the curriculum to be gone through in order to obtain the respective qualifications of these bodies, which qualifications are mentioned in Schedule A of the Medical Act of 1858 and admit to the Medical Register, and that these courses of study of chemistry, physics, and biology pursued at institutions which are not universities or recognised medical schools or scientific institutions approved by the Medical Council do not secure that the persons who pursue such courses of study and who afterwards obtain the qualifications of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow possess the requisite knowledge and skill for the efficient practice of their profession.

III. That many courses of study in the subjects of physics, chemistry, and biology are accepted by the Society of Apothecaries of London (which under Section V., Sub-section (i.), of the Medical Act, 1886, grants qualifications admitting to the Medical Register), in terms of the fourth paragraph on page 3 of the regulations of the Society of Apothecaries, as parts of the curriculum to be gone through in order to obtain the qualification of this body, which qualification admits to the Medical Register; and that these courses of study of physics, chemistry, and biology pursued at institutions which are not universities or recognised medical schools or scientific institutions approved by the Medical Council, do not secure that the persons who pursue such courses of study and who afterwards obtain the qualification of the Society of Apothecaries of London possess the requisite knowledge and skill for the efficient practice of their profession.

IV. That as the University of Oxford grants its medical degrees after examination only, and without evidence that any courses of study in the subjects of the curriculum laid down by the Medical Council have been undergone by candidates for these degrees; the possession of such degrees, which are qualifications admitting to the Medical Register, does not in terms of Section XVIII. of the Medical Act of 1858 secure that the persons holding the degrees possess the requisite knowledge and skill for the efficient practice of their profession.

V. That the attention of the governing body of the University of London, which is at present engaged in framing regulations under the new constitution of the University, be directed to the requirements of the Medical Council regarding the medical curriculum, and to Clauses XVIII. and XX. of the Medical Act of 1858, which impose on the Medical Council the duty of insuring that the courses of medical study pursued by candidates for a registrable qualification shall be sufficient to insure along with an adequate standard of examination that the persons who obtain the qualification shall possess the requisite knowledge and skill for the efficient practice of their profession.

VI. That the University of Durham, by recognising all the courses of study which are recognised by all the licensing bodies in Schedule A of the Medical Act, 1858, accepts many courses of study in the subjects of physics, chemistry, and biology which have been recognised by the Conjoint Board of England, but have not been approved by the Medical Council, as parts of the curriculum to be gone through in order to obtain the medical degrees of the University, which are qualifications mentioned in Schedule A of the Medical Act of 1858, and admit to the Medical Register; and that these courses of study of chemistry, physics, and biology pursued at institutions which are not universities or recognised medical schools or scientific institutions approved by the Medical Council do not secure that the persons who pursue such courses of study, and who afterwards obtain the medical degrees of the University of Durham, possess the requisite knowledge and skill for the efficient practice of their profession.

VII. That the President be requested to communicate the foregoing resolutions of the Council to the licensing authorities to whom they respectively refer, and that the President be further requested to call the earnest attention of these bodies to the obligations under which the Council will be placed in November next to represent to His Majesty and His Most Honourable Privy Council in terms of Section XX. of the Medical Act of 1858 the insufficiency of the courses of study required by these bodies from candidates who seek their registrable qualifications and to express the hope that when the Council meets in November it shall receive assurances from these bodies that they will give effect to the Council's requirements as to courses of study and curriculum and thus relieve the Medical Council from the necessity of making any such representation.

VIII. That the University Courts of the Scottish Universities be requested to frame new ordinances by which the provisions of Clause X. of the present ordinances which permit that in certain cases the full period of the medical curriculum may be four years only shall be abrogated and that the new ordinances shall provide for a five years' medical curriculum being in all cases required.

IX. That the Education Committee shall in future be designated the Education and Curriculum Committee, and that in addition to its present duties the committee shall report annually to the Medical Council regarding the curricula of the licensing bodies.

(*Signed by* DR. MC VAIL.)

### *Minority Report.*

I. We, having considered the numerous differences in detail as to the courses of professional study required by the several qualifying bodies, are of opinion that, even if it were desirable, it is impossible to obtain absolute uniformity, and recommend the Council to withdraw its late resolution requiring the approval by the General Medical Council of the scientific institutions recognised as places of study by the qualifying bodies.

II. We are of opinion that the powers claimed by the Council in this particular do not exist.

(*Signed by* MR. BRYANT *and* DR. NORMAN MOORE.)

The PRESIDENT informed the Council that two opinions relating to the subject before them had been obtained from Mr. Muir Mackenzie, their counsel. One related to the curriculum, and the other had a very important bearing on the report and the discussion which might take place on it. They had been put in print, but had been marked "strictly private and confidential." He thought, however, that they should form a part of the papers in the case, and he moved accordingly.

Mr. BROWN: Should these be made public?

The PRESIDENT: This is a public question, and I have no doubt that the opinions will be referred to repeatedly during the course of the discussion.

The motion was agreed to, and the two opinions, as follows, were entered on the minutes:—

### I.

### *Question submitted by the Curriculum Committee.*

Should the Medical Council be of opinion that a licensing body, whose qualification or qualifications admit to the Medical Register, accepts courses of study pursued by candidates for its qualification or qualifications, which courses of study do not, in the opinion of the Medical Council, secure that the candidates who have undergone them and who, after passing the qualifying examination of the licensing body, receive its registrable qualification or qualifications, shall possess the requisite knowledge and skill for the efficient practice of their profession, is the Medical Council empowered to represent to His Majesty and His Most Honourable Privy Council that the qualifications granted by the licensing body are not such as to secure that the persons who receive them possess the requisite knowledge and skill for the efficient practice of their profession?

### *Opinion.*

My opinion is that the General Council can, if necessary, dissociate courses of study from examinations, and in the case above described can represent to the Privy Council that the courses of study to be gone through by candidates for the qualification of the licensing body are not such as to secure that the persons who receive the qualification possess the requisite knowledge and skill for the efficient practice of their profession. M. MUIR MACKENZIE.

February 22nd, 1902.

### II.

### *Representation to the Privy Council; Opinion.*

The first question in which, as I understand, my opinion is desired is whether, in the case of one or more of the licensing authorities, if the General Council takes no exception to the qualifying examination prescribed by the Medical Act, 1886, and the standard of proficiency required from candidates at those examinations, the General Council has stated its determination to recognise only scientific institutions that have specially been approved by the Council itself The Colleges hold that the Council has no power under the Acts to impose such requirements on them, and generally that the Council, may, on such points, only tender advice which a licensing body may accept or decline

. What then, actually are the powers of the Council in regard to the matter in consideration? The General Medical Council derives all its authority from the Medical Acts, particularly the Acts of 1858 and 1886 and the Council is bound to administer these Acts The preparation of a Register containing the names of all practitioners duly qualified in terms of the Act was the first important work to be undertaken by the Medical Council, and the supervision of the Register remains its chief duty The Act requires the Council to enter in the Register the names of persons who have received medical degrees and diplomas from bodies that are mentioned in Schedule (A) of the Act of 1858, and, since 1886, persons who have received diplomas from conjoint boards of medical and surgical corporations as defined in the Act of 1886 or of single corporations under conditions as to additional examiners appointed by the Council as provided for in that Act At present there are 12 universities in the United Kingdom, and one corporation, each of which grants qualifications that entitle to registration, there are three conjoint boards, each of which gives qualifications that must be registered on application by the recipients, and there are two single corporations, which having been provided with the necessary additional examiners, also confer registrable qualifications In all then, there are 17 bodies in the United Kingdom whose graduates and diplomates are entitled to be put on the Register

The question then is, has the Council acted without legal power or do the Acts of Parliament confer upon it the power which it claims?

It was open to Parliament in framing the Act of 1858 to require the Medical Council to register every graduate and diplomate of every one of the bodies, or combinations of bodies, without any question and without any voice as to the conditions of study and examination, each body being a law to itself Or the Act might have given to the Council absolute powers as to receiving or declining any of the various degrees and diplomas The Council might have had power to strike off and to readmit any qualification according to its dissatisfaction or satisfaction with the conditions under which the qualification is granted Neither of these courses was adopted, but the Act did not leave the bodies free to confer qualifications entirely as each might think fit and on any terms it might individually decree The Act (Section XXI) confers on His Majesty and the Privy Council the power if they see fit to order that any qualification granted by any of the bodies may cease to confer any right to be registered under the Act and His Majesty and the Privy Council have also the power of revoking any such order of deprivation But the Privy Council cannot act thus on its own initiative it can act only as regards an order for deprivation on a representation by the Medical Council No provision exists by which such representation can be made by any authority other than the Medical Council and this representation must be that the course of study and examinations to be gone through, required by the college or body regarding which the representation is made, are not such as to secure the requisite knowledge and skill for the efficient practice of the profession The manner in which the Medical Council is to acquaint itself with the courses of study and examinations is laid down in Section XVIII. of the Act which gives the Council the power to ask from the several Colleges and bodies in Schedule (A) from time to time such information as the Council may require as to the courses of study and examinations to be gone through in order to obtain the respective qualifications and generally as to the requisites for obtaining such qualifications, and any member or members of the Council, or any person or persons deputed by the Council, may attend such examinations Section XX of the Act is —

"In case it appear to the General Council that the course of study and examinations to be gone through in order to obtain any such qualification from any such College or body are not such as to secure the possession by persons obtaining such qualification of the requisite knowledge and skill for the efficient practice of their profession it shall be lawful for such General Council to represent the same to Her [His] Majesty's most Honourable Privy Council"

The Council thus has laid upon it the obligation of deciding this point as to the standards of study and examinations Under the Act of 1858 the voice of the Council alone can be heard by the Privy Council as to this point in regard to the sufficiency or insufficiency of study and examinations There appears to be no provision in Section XXI whereby the Privy Council can receive evidence or opinions relating to study and examinations otherwise than through the Medical Council

But in the Act of 1886 Section 4 modifies Section XXI of 1858, and is as follows —

"4—(1) If at any time it appears to the General Council that the standard of proficiency in medicine surgery, and midwifery, or in any of those subjects or any branch thereof required from candidates at the qualifying examinations held by any of the bodies for the time being holding such examinations is insufficient the General Council shall make a representation to that effect to the Privy Council and the Privy Council if they think fit, after considering such representation and also any objections thereto made by any body or bodies to which such representation relates may by order declare that the examinations of any such body or bodies shall not be deemed to be qualifying examinations for the purpose of registration under the Medical Acts, and Her Majesty with the advice of Her Privy Council, if, upon further representation from the General Council or from any body or bodies to which such order relates it seems to her expedient so to do, shall have power at any time to revoke any such order

"(2) During the continuance of any such order the examinations held by the body or bodies to which it relates shall not be deemed qualifying examinations under this Act and any diploma granted to persons on passing such examinations shall not entitle such persons to be registered under the Medical Acts, and any such body shall not choose either separately or collectively with any other body a member of the General Council and the Member (if any) for the time being representing such body in the General Council shall, unless he was chosen by such body collectively with any other body not subject to an order under this section, be suspended from taking part in the proceedings of the General Council

Thus the Privy Council must hear and consider "any objections thereto made by any body or bodies to which such representation relates Does this apply to the sufficiency or insufficiency of the courses of study of Sections XVIII and XX of the Act of 1858, and the first section of the Act of 1886 is that the Act is to 'be construed as one with the Medical Acts'? Apparently, regarding courses of study, the Medical Council only can be heard by the Privy Council

How, then should the Medical Council proceed in this relationship which it bears to the Privy Council and the bodies enumerated in Schedule (A)? Obviously its primary duty with regard to the bodies is to inform them as to its opinions regarding the courses and standards of study, and the scope and standard of examinations which each body should as a minimum require To refrain from doing this would be unfair and vexatious, were it to deny information as to the standards it approves the bodies in ignorance of its requirements would necessarily act each according to its own judgment; insufficiency here and there might occur, and the Council might be repeatedly reporting to the Privy Council or otherwise would be neglecting its duty To formulate therefore, a minimum course of study was obligatory on the Council as one of its earliest duties when it was first constituted, and that duty it performed, and has continued to perform during the 43 years of its existence It has always set forth a curriculum, which it has amended and extended from time to time with the progress of education and the advancement of medical science Had the Council refrained from formulating a minimum curriculum and had it in the absence of such a curriculum made a representation to the Privy Council of insufficiency of study on the part of any body in Schedule (A), it appears probable that the Privy Council would have ordered the Medical Council to lay down forthwith a minimum curriculum of study for the guidance of the bodies The present action of the Royal Colleges of Physicians and Surgeons of England in refusing to regard the Medical Council's resolutions as other than mere recommendations which they may adopt or ignore, is contrary to the view above expressed as to their duty under the Medical Acts It seems inconsistent with the conduct of their own representatives on the Council who always before the present differences arose, took a large important, and enlightened share in the formulation of a curriculum

Clause XVIII of the Medical Act of 1858 reads as follows —

"The several Colleges and bodies in the United Kingdom mentioned in Schedule (A) to this Act shall from time to time, when required by the General Council furnish such Council with such information as they may require as to the courses of study and examinations to be gone through in order to obtain the respective qualifications mentioned in Schedule (A) to this Act and the ages at which such courses of study and examination are required to be gone through, and such qualifications are conferred, and generally as to the requisites for obtaining such qualifications, and any member or members of the General Council or any person or persons deputed for this purpose by such Council, or by any Branch Council may attend and be present at any such examinations

The Medical Council is to obtain information regarding the courses of study required by, and the standard of the examination conducted by, the various licensing bodies It is clear that any registrable qualification is not to be granted after study alone or after examination alone Were examination ever to become the only safeguard to the Medical Register, it would require to be as to scope and character, entirely different from any examination that has ever been conducted by any medical licensing authority in the United Kingdom All the present examinations would be altogether inadequate as they can only test here and there the knowledge of a candidate They do no more than merely sample his attainments A curriculum of study is assumed in the case of every student He produces certificates that he has spent a prescribed time in the study of a large number of subjects, and in addition that he has given a prolonged attendance at clinical and other practical work It is on this basis that the examiners investigate his proficiency in any subject Examination can never adequately guard the portals of the profession where the courses of study have been insufficient Therefore it is that the obligation is imposed on the Medical Council to regard both study and examination to the extent of securing the possession of the requisite knowledge and skill in the case of every person presenting a qualification which they are to register If the courses of study of the three science subjects recognised by the English colleges are unsatisfactory in this respect then the mere standard of examination cannot supply the deficiency

The institution of the Medical Register was for the protection of the public only persons of sufficient skill were to be admitted to it 43 years have passed since the first Medical Act became law and in the interval medical science has advanced at a rate never equalled in the former history of the world The first curriculum required by the Medical Council differs greatly from that required to-day The Council has consequently from time to time increased its requirements An adequate knowledge of physics and biology is essential in the study of modern physiology pathology, and bacteriology as these in turn are essential to medicine and surgery The new subjects should be studied under conditions not less stringent and exacting than those that apply to the other subjects of the curriculum

### *Conclusions by the Committee.*

I The Medical Council has decided that the scientific institutions other than universities or recognised medical schools, at which the courses of study in chemistry, physics and biology may be taken by students as part of their medical curriculum are to be approved by the Medical Council prior to registration in the Students' Register of students commencing their studies at those institutions

II The Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England, notwithstanding repeated remonstrances made to these Colleges by the Medical Council, continues to recognise courses of study in a large number of teaching institutions that have not been approved by the Medical Council and does not now require evidence of registration in the Students' Register, nor that the students shall have passed a preliminary examination recognised by the Medical Council but a preliminary examination the recognition of which is determined by itself

III The Conjoint Board of the Royal Colleges of Physicians of Edinburgh the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, although requiring evidence that candidates who present themselves at their first professional examination which includes the subjects of physics chemistry, and biology, shall have been registered in the Students' Register, and thus must have taken the courses of study in these the letter that came from Ireland during last session—the letter in which the authorities of Trinity College, Dublin, intimated that they would in future consider only the interests of medical students in Ireland without any reference to what the General Medical Council might determine. The views of Trinity College would be the view of the licensing bodies generally. Was it, then, any great wonder that the Council should have taken steps such as it did last session to settle this dispute between it and the English Royal Colleges? The report of the special committee just presented stated fairly and accurately the position of the Medical Council with regard to the licensing of practitioners. It showed what might cause a good deal of astonishment to many members of the Council—namely, widespread non-conformity with the Council's requirements. The English Conjoint Board, the University of Oxford, the University of London, the Scottish Conjoint Board, the Apothecaries' Society of London—all these deviated from the Council's requirements in their own special regulations. For this state of affairs the Council, he maintained, must take some blame upon itself. It ought to have taken action long ago. The striking diversity on the part of Oxford should not have been allowed to continue. No doubt Oxford had stood in a peculiar position, for it was only a few years since that it began to show development into a medical school. But matters were different now, because Oxford was rapidly becoming an important medical centre. As regards the University of London, that institution was at present being reconstituted. If the English Conjoint Board were at one with the Council the difference that the Scottish Conjoint Board's regulations showed would disappear; and he had no doubt that whether the English Conjoint Board conformed or not to the Council's requirements that difference would disappear. He wished to emphasise the fact that not one of the licensing bodies in the three kingdoms except the English Conjoint Board had declared that it would not in any way be bound by the requirements of the Council; not one of these bodies except the English Conjoint Board had stated that the Council had no power to make regulations. The English Conjoint Board stood alone; it alone of all the licensing bodies had defied the General Council. Now what was to be done? That question involved the other question of what the powers of the Council were Had the Council authority over these licensing bodies or not? If it had no authority what an immense amount of time and money had the General Medical Council wasted. But had the Council no authority? It appeared to him that there was not the slightest doubt that it had power—that it was the supreme body so far as indicating what was the minimum amount of knowledge and skill which a person must possess before being allowed to practise They were not to dictate uniformity, but they were to say what was the least amount of study and examination necessary for a uniform qualification. Then if these courses of study were not "sufficient" the Council had the power to make a representation to that effect to the Privy Council It was part of their duty to do so. They should not be influenced by any fear that the Privy Council might humiliate them; they were not to be afraid to do their duty because the Privy Council might snub them. They were to do their duty; the Privy Council could do theirs. Now the General Council were satisfied that the course of study sanctioned by the English Royal Colleges for the first year's subjects was "insufficient" Although they had not yet said so in actual words, they had said so by implication, for they had directed their Registrar not to register in the Students' Register persons coming from the English Royal Colleges' preliminary examination. It was quite true that the Council had left the matter in the hands of their Students' Registration Committee. That committee, however, was one which dealt with suspicious, with doubtful, cases. It had been given to that committee to keep the door open to candidates coming from the Royal Colleges' examination, but the General Council had publicly decided, and by a large majority too, that the Colleges' course of study was "insufficient." Having recorded their opinion that there was insufficiency, what were they to do? They did not require to associate study with examinations before they could make a representation of insufficiency. The opinion of Mr. Muir Mackenzie showed clearly that, if necessary, the Council could dissociate courses of study from examinations. The Council had no power to inspect the schools recognised by the English Conjoint Board, and he asked if there was need for such inspection. He did not think so. As regards the course of study in connexion with the various licensing bodies they could go to the official papers issued by these bodies to find out what their regulations were. And so in connexion with the English Royal Colleges. From the syllabus of the Royal Colleges which he held in his hand he saw that these Colleges were recognising a vast number of schools, not universities or medical schools, and that there was considerable difference in the subjects of the first and second examinations. He found, moreover, that the candidate need only give evidence that he had "received" instruction, but there was no information afforded as to how the student was to study or what he was to do during the year, and there was no word to indicate that the four subjects of chemistry, biology, physics, and pharmacy might not be taught by one man.

Dr. Norman Moore: There is not the slightest doubt that these subjects would be taught by different teachers.

Dr. McVail protested that there was no indication as to how these subjects were to be taken and how much of them were to be taken. They knew, then, that they did not know the condition of these Colleges as regards the subjects of study. It was that information they wanted. They ought to obtain information as regards the course of study. He found that the Conjoint Board's programme showed, for instance, that physics was not mentioned except as chemical physics. Two questions were set in chemical physics and the student did not require to answer more than one of them. But the Colleges' physics were chemical physics—not the physics of the General Medical Council. As regards biology there were no written questions prescribed, yet everyone knew that oral examination in biology was not sufficient. What he had just mentioned convinced him that the Council had quite sufficient information as regards the courses of study prescribed and that the Medical Council was within its rights to order its Registrar to cease to register students from the Royal Colleges. But the Council could not stop here. They must go further or they must recede. The minority recommended that they should rescind their resolution. Would they go back on their work of the past 12 years? If they did not they could do nothing else than fulfil their duty under Section 20 of the Medical Act A great deal had been said during the discussions on this subject about ancient charters, but what he maintained was that all the rights anybody could have under any charter when these conflicted with the provisions of the Acts of 1858 and 1886 had disappeared or could be exercised only in conformity with these Medical Acts. No doubt some of these charters were venerable, but that should not prevent the Council from doing their duty, which was to care for the Medical Register and see that no one unfit was to be admitted to it, or if admitted to it was not retained on it. Should this General Medical Council perform its duty to the public or not? Were these English Royal Colleges to frighten the Council by telling them that they had no power to lay down rules that the medical licensing bodies were bound to observe? It was time to say otherwise, for if the present condition of affairs was passed over without the necessary action on the Council's part, within the next twelvemonth the control of medical education by the General Council would be practically defunct. The Privy Council alone, he believed, could now provide a solution of the difficulty.

Dr. Young formally seconded the motion.

No one rose at once to continue the discussion, and the President asked whether any member wished to speak.

Dr. Norman Moore, after being specially named and after a pause, rose and said that any remarks which he might make at that stage of the debate would be brief. Dr. McVail had given a full account of what the Special Committee had done, and he had to thank him for the great consideration which he, as chairman, had shown to the minority in the committee Every courtesy had been shown to that minority, and no attempt whatever had been made to slur over their objections. Both Mr. Bryant and he had sat on the committee not as representatives of the English Royal Colleges but as members of the General Medical Council, and he considered that the report as now presented was much better than it was in its first draft because of the heed which had been given to the minority's views on certain portions which had been submitted for the committee's approval. He wished the Council to know this. Dr. McVail in his very able speech had put the case with all the force with which it was capable of being put. But there were some chance phrases in that speech which should not be passed can nevertheless if dissatisfied with the course of study prescribed and accepted by such licensing authorities represent to the Privy Council that the course of study is defective (I propose to use the single expression "defective to avoid repetition of the longer words in the Act—"not such as to secure the possession by persons obtaining such qualification of the requisite knowledge &c) within the meaning of Section XX of the Medical Act 1858

On this question my opinion is as follows —

The enactments in the Medical Act 1886, do not supersede the enactments in the Act of 1858 Both sets of enactments are to be read and applied as if they were contained in one Act The Legislature has not made examination the test, and the only test of the possession by a candidate for admission to the medical profession of the necessary knowledge and skill

Although in Sections XVIII and XX of the Act of 1858 the words used are courses of study and examinations,' it will be observed that in Section XXI of the Act the words are "course of study or examinations, or the mode of conducting such examinations' Again, in Section XVIII of the Act the Colleges and bodies mentioned in it are required to furnish information as to the ages at which courses of study are to be pursued, and generally as to the requisites for obtaining the qualifications

In my opinion the Legislature has recognised and had regard to the principle that mere examination cannot be a sufficient test of professional knowledge and skill if the courses of study have been insufficient and if in the opinion of the General Council the courses of study required by one or more of the licensing authorities are defective, the General Council can so represent to the Privy Council, notwithstanding that the General Council makes no representation on the subject of the examinations

2 The second question is this If one of the licensing bodies accepts as part of the course of study required from a candidate a course of study pursued in particular subjects at another institution then if the General Council does not approve of the institution as a teaching body, can the General Council represent to the Privy Council that the course of study of the licensing body is defective?

On this question my opinion is that if the General Council is of opinion that the teaching and course of study in the particular subjects at the institutions whose courses of study are accepted by the licensing body are inadequate and defective, then the General Council would be within its powers in representing to the Privy Council that the course of study required by the licensing body is defective So if one of the licensing bodies fails to exact from its candidates a sufficient or adequate course of study and teaching in particular subjects such as chemistry and physics, the Council would be within its powers in representing to the Privy Council that the course of study required by the licensing body is defective

But in a case in which the ground of objection by the General Council to the course of study required by a licensing body is that the teaching and course of study in special subjects at a particular school is accepted as part of the licensing body's curriculum the Council could not properly make a representation to the Privy Council unless satisfied that the teaching and course of study at the school is in fact defective

3 The third question is as to the powers and procedure of the Privy Council as to which my opinion is as follows —

The Act of 1858 empowers the Privy Council, upon the representation of the General Council, if it see fit, to order that the qualification granted by a licensing body shall cease to confer a right to be registered

For the purpose of exercising this power the Privy Council would not be confined to considering the facts and views presented by the General Council The Privy Council would have power, and in accordance with the procedure which it generally adopts would hear the licensing body or bodies of whose courses of study complaint is made and would not make an order depriving or suspending the qualification of the body from admission to the Register without being satisfied that the complaint that its course of study was defective was substantially justified

4 The fourth question is substantially as to the extent of the duty and power of the General Council as to prescribing a curriculum or course of study which each licensing authority is to observe

On this it will be observed that the enactments in the Medical Act of 1858 do not direct the General Council to prescribe courses of study, or (still less) to prescribe that every licensing body is to require as a minimum a specially defined course of study The provisions of the Act leave each licensing body to prescribe its own course of study the duty and power of the General Council being to exact information as to the courses of study and examinations, and to depute members of the Council and other persons to attend the examinations It follows that the General Council's statutory duty is, strictly speaking, limited to requiring defects in the courses of study to be made good to the Council's satisfaction and improvements which the Council can specify, to be made in the courses of study and examinations

A licensing body which declined to adopt in all respects a curriculum prescribed by the General Council would not, in my opinion, be deprived by the Privy Council of the right to have its qualifications admitted to the Register if it could establish to the satisfaction of the Privy Council that its prescribed curriculum was nevertheless not defective

5 The fifth question has regard to the particular licensing bodies mentioned in the committee's report, on which my opinion is as follows —

The cases of the University of Oxford and the University of London are simple In effect these universities do not require any special course of study of the nature which in the General Council's opinion a candidate for a qualification ought to be required to pursue Clearly, the General Council can make a representation to the Privy Council in relation to these universities unless effectual provision is made by those universities to the satisfaction of the General Council for the improvement of the courses of study required by the universities

As regards the other licensing bodies, the question relates in principle to the acceptance by each licensing body as part of its prescribed curriculum of a course of teaching or study at an institution of which the General Council does not approve As I have already stated my opinion is that if one or more of these bodies directly or *indirectly accepts as part of the course of study required by a candidate* for its qualifications a certificate that the candidate has pursued a course of study at another teaching institution then if the General Council is of opinion on sufficient grounds, that the teaching and course of study at the teaching institution is inadequate and defective the Council can represent to the Privy Council that the course of study of the licensing body is defective, but it would be for the Privy *Council in the exercise of its uncontrolled discretion to decide if, and if* so to what extent, effect should be given to the representation

4 Temple Gardens, E C, Feb 22nd, 1902 M MUIR MACKENZIE

Dr MCVAIL, in then moving that the portion of the report which he had read be adopted, said that he would state the views of the majority of the committee, leaving it to the minority to present their own case The first point he wished to direct the attention of the Council to was that nearly 12 years ago they decided to have the five years' curriculum of study, and decided, moreover, that physics and biology should be added to the curriculum That had been passed by general consent So far as he knew there was no evidence that there was any minority or any opposition whatever, at any rate, there was *no adverse* statement from any of the licensing bodies or from any representative of these bodies that there was disapproval of the action of the Council Three years later the Council had seen fit to stiffen its regulations The Education Committee of the day recommended that they should codify their resolutions regarding medical studies, dividing them into requirements and recommendations The Council had adopted that suggestion, and it had codified its resolutions as regards study into requirements These requirements were entirely requirements as to study and the Council therefore had assumed that it could make a representation to the Privy Council in the matter of study alone, without any reference to examinations, that was to say, if the study was "insufficient" the examination, whatever it might be, could not make up for deficiency in the study That was in 1893 In that year there was a matter in dispute as to the time at which students should be registered—whether the registration should take place before or after the preliminary examination, but as the Colleges gave way to the views of the Council he need not go into that matter on the present occasion After the lapse of five years—that was to say, in 1898—the Council were made aware that the Conjoint Board of England had recognised a very great number of teaching institutions, many of them no more than grammar schools, as places in which chemistry, biology, and physics might be taken by intending medical candidates This information, he reminded the Council, came to them in a letter sent by the Royal College of Surgeons in Ireland, and had been reckoned so important that a remit was made to the Education Committee who subsequently reported that many of the schools recognised by the Colleges were not recognised by the Council and were not inspected for the purposes of medical education The Council had consequently requested the Royal Colleges to reconsider their position, but they were met with a refusal On this the matter again came under consideration and the Council decided that the institutions in which the first year's subjects were taken must not only be recognised by the licensing bodies but be approved by the Council The English Royal Colleges refused to recognise any such right of approval to exist in the Medical Council, and not only that, but they stated that the Council had no power whatever to make requirements or resolutions that were binding on the licensing bodies, and if they did make such the bodies might give effect to them only if they saw fit That was a new feature in the case No longer was it a mere refusal to submit to approval, but a decided expression of opinion that the General Medical Council had no power whatever over the medical curriculum that any body under Schedule A might choose to adopt The Council then passed one of the most important resolutions ever placed upon the minutes, as in effect it refused to admit to registration on the Students' Register persons who took their course of the first year's subjects at institutions of which the Council had not approved The next step was that the Royal Colleges absolved all candidates for their diplomas from the necessity of being registered in the Students' Register—and the preliminary examination passed by students of the Royal Colleges was thus no longer the preliminary examination recognised by the Council These Colleges had thrown away every shred of dependence on the General Medical Council, and acted as if that Council did not exist at all Small wonder, therefore, was it that other bodies had begun to move in the same lines and to say that they were not to be bound by the requirements of the Council if the English Conjoint Board were to be allowed to act independently of the General Council Let them remember when the first Medical Act was brought forward there was not the smallest intention of taking away any of the rights and privileges of any of the licensing bodies, whether universities or colleges. It was true that a few years after the Council was formed there was a very severe struggle and a heated debate, principally emanating from the Scottish Members, in favour of having full authority so as to enforce the edicts of the Council. The Council, however, did not gain that point; it was defeated and he had always thought that since that time it had been fully recognised that the Council had no official power to compel the bodies to carry out its behests, that it could go no further than make recommendations. The Council had not the power, and he did not believe that the Government would give it the power, to bring down all the bodies to a level. At present there was competition amongst the bodies to raise the standard of medical education and he did not think that the English Royal Colleges had borne themselves ill in this competition. He believed that it would be a great mistake if the Council determined to go to the Privy Council to find fault with the Colleges. The Colleges themselves had no reason to fear such an appeal. They welcomed inquiry into the work they were doing and felt that the more it was inquired into the more would it be valued. His regret would be for the Council, for he felt that it had a weak case and would be sure to get a snub from the Privy Council.

Dr. P. HERON WATSON read to the Council a memorandum prepared by the Registrars of the Scottish Conjoint Board. It appeared, said the memorandum, that the regulations of the board did not conform to the requirements of the Council in three particulars, viz.—(1) that they recognised four teaching institutions in Scotland not recognised by the Council, two for physics, chemistry, and biology, one for physics and chemistry only, and one for chemistry only; (2) that they recognised those teaching institutions in England for physics, chemistry, and elementary biology which were recognised by the English Board; and (3) that they exempted from the first professional examination candidates who had passed the corresponding examination of the English Board and might, therefore, indirectly recognise the teaching of the institutions recognised by that board which were not approved by the General Medical Council. The registrars wished to remark that the Committee of Management had no desire to depart from the time-honoured usage of recognising for teaching purposes any institutions other than the ordinary medical schools, university and extramural. In making the departure they simply followed the lead of the English Board. At the same time they had to say that all the four institutions referred to were carefully inspected by the committee and the accommodation and appliances for teaching were found to be satisfactory. At the time these institutions were recognised the policy of the General Medical Council with regard to such recognition was, or appeared to be, much less pronounced and decisive than the form which it had recently assumed and the registrars believed that in according recognition the committee were quite unaware that they were running counter to the desire of the Council. The board had, however, insisted that the course of study should be five years from registration and that this should precede recognised study. As to the second point, if the English Board reduced their list of recognised teaching institutions to meet the views of the Council the Scottish list would *ipso facto* be reduced to the same extent. As a matter of fact, the registrars affirmed that no certificates from the schools in question had, so far as they knew, been submitted to them for inspection, and that the recognition of these schools was therefore, as far as they were concerned, only in theory. As regards the exemption of candidates from the first examination in virtue of their passing it at the English Board, it might also be said that such cases now rarely presented themselves, and the registrars could find no case in which the applicant so exempted had studied at one of the institutions in question.

Sir HUGH BEEVOR wished to say that while he felt perfectly sure that nothing was in the mind of the Apothecaries' Society of London which in any way would alter the relations of that society to the General Medical Council, he strongly deprecated proceeding on the lines of the recommendations submitted by the Special Committee.

Sir HECTOR CAMERON said that the non-conformity of the Scottish Conjoint Board in respect to the requirements of the Council was really more apparent than real. It was alleged that the board's regulations on two points differed from the regulations of the General Council. The first allegation was that the board recognised certain courses of chemistry, physics, and biology, before registration, but to the regulation permitting that there was attached this important proviso—"Provided always that the period of professional study after registration shall not be less than five years." That being the regulation of the Scottish Conjoint Board, they were certainly no sinners against the requirements of the Council. The second allegation against the Scottish Conjoint Board was that they recognised the early examination of the Conjoint Board of England. That allegation had truth in it, but the regulation was an old one. It had been on the by-laws from the formation of the Scottish Conjoint Board, and had not been added to or taken from. So their position was what it had always been.

Mr. YOUNG, replying to the President, said that as no substantial objection had been taken to that portion of the report now before the Council he would not take up time by commenting on anything that had been said.

Sir WILLIAM GAIRDNER intimated that he had no objection to the committee's report to the extent that it was before the Council, but he wished it to be known that he had the strongest objection to all the recommendations of the committee so far as they proposed appeal to the Privy Council, and that if these recommendations were brought forward he would oppose them to the utmost.

Dr. MCVAIL, in closing the debate, thought that nothing need be said by him in reply, because the report so far as the Council were asked to adopt it was merely a statement of facts. This, however, he might say in regard to Dr. Payne's remarks: the committee could not leave out Oxford University from their consideration, because Oxford University was a licensing body under the Medical Act of 1858, and no objection had been taken in the committee to the inclusion of Oxford.

Dr. PAYNE explained that his contention was that the report applied to the Royal Colleges. He had made no objection to the inclusion of Oxford. What he had said was that the Royal Colleges stood in one category, and all the other licensing bodies in another.

The Council then voted on the motion, when it was found that 17 were for it and only four against it.

Accordingly, Dr. McVail's motion that the committee's report as far as page 53 (the end of "Conclusions of the Committee") be adopted, became the finding of the Council.

After a quarter of an hour's adjournment for tea,

Dr. MCVAIL said that during the two days the Council had been in session he had heard a good deal from colleagues as to their views on the subject before them. The proposal to go to the Privy Council with a representation of the "insufficiency" of the curriculum of the Royal Colleges was undoubtedly an extreme step to take. It was, however, equally a difficult matter for the Council to stand still. He had been thinking over the situation, and had been led to question whether any third course was open to them. He had found that some members of the Special Committee who in committee had approved of the recommendations submitted in the report were now in doubt as to whether the time had come formally to ask the Council to adopt these recommendations. As a matter of fact, he found that some of the five members who formed the majority of the committee were not now prepared to support these recommendations, or even to ask the Council to pass them during the current session. In these circumstances, and considering the gravity of the step involved in passing a resolution to make a representation to the Privy Council, he was prepared to suggest that the Council might take the third way open to them. What he meant was that they might delay consideration of the committee's recommendations and at the same time decide that the Council should order an inspection of all the examinations of all the licensing bodies who included chemistry, physics, and biology as the early subjects in their course of study, and also ask from every licensing body full and definite information as to all the teaching institutions which they recognised, the nature of the teaching conducted thereat, the ages of the students, the qualification of the teachers, &c. They were entitled to ask for such information under Section XVIII. of the Act of 1858. If the Council were of opinion that consideration of the recommendations should be delayed, he was over without notice. Dr. McVail had spoken of the English Royal Colleges defying the General Council. "Defying" was a word that should not be used. The Royal Colleges would never be in the frame of mind to defy the General Council, and they in no way offered defiance. The question between them and the Council was a question of the discussion of matters of public importance, and they might differ in opinion as regards it, but they did not defy the Council. They differed for the reasons given. They accepted the Council's reasons with respect, and they expected that the Council would receive their reasons with equal respect. Dr. McVail had said that the course of study prescribed by the Royal Colleges was "insufficient." How was that to be known? Surely the knowledge must be derived from observation, study, and inquiry. All the schools recognised as teaching institutions by the Royal Colleges were good, and before the Council said that the College's course of study was insufficient or that the schools were improper there ought to be inquiry. Unless the Council investigated the whole subject, he maintained that it was not right to assert that the secondary school was not a suitable place in which to give preliminary medical education, and that its course of study was insufficient. The Royal Colleges did not think that the course of study they asked for was insufficient. They had examined the schools that were on their list, and until the Council did so too they would not be on an equal footing with the Colleges. There was no practical difference between the curriculum which the Colleges recognised and that which the Council recognised. The Colleges did not propose to introduce a class of "juniors," and all talk about "boys" should cease. He believed that the course which the Colleges had followed was the best course, and therefore he implored the Council to get rid of the idea about the introduction of little boys and such like. Dr. McVail was puzzled as to the amount of work that was to be done in the preliminary subjects. He must remind him that the curriculum of study and examinations could not be separated. The two had to be considered together, and if the student had to pass a definite examination that was security enough to obtain sufficient attention being given to study. Therefore the objection as to possible inadequacy of study fell to the ground. He felt reluctant to say anything about the proposed appeal to the Privy Council, and he felt reluctant to deprecate such an appeal because it would mean inquiry. The Colleges had their duty to do. Their conduct would bear investigation. Their reasons for adopting the course they had taken were perfectly sound They would like to agree with the Council, for the object of both—the making of medical education thorough and efficient—was the same, but as regards the course which the Colleges had taken in respect to the early subjects the Colleges thought that the Council was wrong and that they themselves were right. The only difference which there was between the Colleges and the Council was that the Colleges allowed studies to be pursued at institutions which, after investigation, they thought to be sound places of study. The whole question rested on that point, and if the Council wished to take the course suggested it should go thoroughly into the matter and ascertain if their views were sound. Let it inspect the institutions complained of, but let it do so before going to the Privy Council.

A motion by Dr. Payne for the adjournment of the debate was agreed to, and

The Council adjourned

### Wednesday, Feb. 26th.

The Council resumed, Sir William Turner being in the chair.

In the course of the adjustment of the minutes of the previous sitting the President announced that the writer of the letter with reference to the Midwives Bill which he had quoted was Mr. Heywood Johnstone, M.P., one of the promoters of the Bill.

### *The Debate on the Curriculum.*

The Council resumed the debate on the motion of Dr. McVail for the adoption of the first part of the report of the special committee on the curriculum

Dr. Payne called attention to the references in the report to the University of Oxford In the first place, he took exception to the University being referred to at all by the committee which he held was appointed to inquire only into the differences existing between the Council and the two English Royal Colleges. The relations of the University of Oxford with the Council had always been of the most harmonious character. It was not the case that the university did not recognise the Students' Register of the Council. It recognised the Register and had done more to encourage the Council's action in connexion with it than perhaps any other qualifying body. Every medical student at Oxford was told or advised that he ought to be registered, and it would be found that every medical student there or preparing for the medical profession there was registered. As the university preliminary examination responsions did not altogether meet the views of the Council the university had taken a step which he did not think any other university had taken—namely, that of making a special examination. It was perfectly true that the university did not require the registration of students by the Council as a necessary condition of obtaining a degree. It was not certain that the university had the power to make such a condition, but in any case it would involve a change of a fundamental character. What the university did was to tell the students that they ought to be registered.

Sir Christopher Nixon said that in his opinion the Council would be very unwise if it exercised its powers of intervention in cases where it was satisfied that a high standard of education was maintained—a standard very much higher than any level laid down in the ordinary requirements and regulations of the Council. The duty of the Council was to see that only persons duly educated were allowed to enter the profession, and if the Council was satisfied that a body like the University of Oxford had a higher standard than these regulations and requirements he thought that it would be unwise for the Council to interfere with vexatious restrictions. He thought that it was an extraordinary thing that this special committee should recommend that the President should write an official communication to, amongst other bodies, the University of Oxford and the University of London, instead of politely and courteously telling them that the Council had certain regulations and requirements and asking them in the interests of medical education and in order to secure uniformity to comply with them. If such a communication as was proposed were sent to the Senate of the Royal University of Ireland it would be thrown into the waste-paper basket. As to the general question, there had been some change in the situation. The question now was not merely the question of the scientific institutions recognised by the two English Royal Colleges but the efficiency of the courses of study. After calmly reviewing the situation it seemed to him that in this matter there had been faults upon both sides. The Council had been in error For one thing it had had no information about the institutions to which exception was taken, and in the absence of definite information he did not think that it would be wise to take the matter before the Privy Council. On the other hand, he did not consider that the two Colleges had treated the Council with the amount of consideration to which it was entitled. He believed that the Council had power to put the matter before the Privy Council. He believed the Council had power to deal with medical education in the broadest sense, but it ought to exercise its power with moderation. Was the Council prepared to go before the Privy Council and say that the courses of study in the institutions which the Council did not recognise were defective? Where was the Council to get its information to support such a statement? The Council had not inspected the institutions, and if it attempted to do so its inspectors might be refused admission. There must in this case be mutual concessions. It seemed to him that the Royal Colleges had gone a certain length in the way of concession. Let the Council realise its position. Its position was a strong one. There could be no doubt that the Council had this power to supervise medical education from start to finish, but it should be careful how it exercised it.

Mr. Bryant denied that the Royal Colleges had made any concession in the matter of the visiting of the institutions It had been the custom of the Royal Colleges to visit the institutions and satisfy themselves as to the character of the teaching and the equipment. It was true that a few of the institutions had not been visited, but these were Government institutions under South Kensington guidance which had been inspected by Government inspectors. But behind this question there was the question of the power of the Council to enforce all its edicts. It was perfectly clear to him that name has become well known to the medical profession in Great Britain in consequence of his having founded the Lane lectureship, an annual office the holder of which is required to deliver 10 lectures in the Cooper College, receiving the liberal salary of 2000 dollars. The first incumbent of the post in 1896 was Professor W. Macewen of Glasgow, and he was followed by Mr. Christopher Heath, Dr. Clifford Allbutt, Dr. Senn of Chicago, Sir Michael Foster, and Mr. Malcolm Morris Professor Ball of Dublin is, we understand, to lecture this year. Dr. Lane contributed various papers to the American periodicals and took an active part in the discussions at the San Francisco Medical Society. He published in 1896 an elaborate work on the Surgery of the Head and Neck, a copy of which is in the library of the Royal College of Surgeons of England. Amiable and learned, and absolutely free from professional jealousy, Dr. Cooper Lane was highly respected and well beloved by both the public and the profession in California, and he exercised upon the latter an influence which was always for good. His death will be a great blow to the two institutions which he founded, but we have little doubt that they will rapidly recuperate under the distinguished staff of colleagues whom Dr. Lane had collected around him.

## SEYMOUR GRAVES TOLLER, M.D., M.R.C.P. LOND.

WE regret to report the death of Dr. Seymour Graves Toller of Cairo on Feb. 19th, after an illness of about 10 days' duration, the details of which have not yet arrived. Dr. Toller was 35 years of age. He was educated at Malvern College where he obtained an exhibition. He entered the medical school at St. Thomas's Hospital as a first year's student in 1885, obtaining the entrance science scholarship. From that time his career showed an uninterrupted list of distinctions obtained not only in his own medical school but in the wider sphere of the London University. At St. Thomas's Hospital, amongst his other prizes he gained the Mead medal for practical medicine. In 1886 he was awarded the gold medal in materia medica at the Apothecaries' Hall. In the M.B. examination of London University he secured the University scholarship and gold medal in medicine and in obstetric medicine. In the M.D. examination also he won the gold medal. In 1896 he took the M.R C.P. In the meantime—that is, from the year 1889—he had been actively engaged in various hospital appointments, culminating in that of resident assistant physician to St. Thomas's Hospital for the years 1894 to 1897. At the termination of his three years' office his dearest hopes were gratified by his election as assistant physician to the hospital staff. But the clouds were already lowering over his head. Almost immediately after his appointment he was compelled to resign it on account of the breakdown of his health. He had a severe attack of what at first appeared to be influenza, but in the course of his illness the sputum was found to be teeming with tubercle bacilli. In a few months' time his health was outwardly fully re-established, but it was clearly too dangerous for him to attempt to remain in this country; he accordingly applied for, and obtained, the posts of physician to the Kasr-el-Aini Hospital, Cairo, and professor of clinical medicine in the medical school. There, with the exception of summer visits to this country, the remaining years of his life were passed. He threw himself with all his energy into both the hospital and teaching work, and, in addition, had to satisfy the demands of a rapidly increasing practice. His health refused to bear the strain and a few months ago he resigned his hospital appointments.

Dr. Toller was known to many outside his profession as a brilliant musician. For many years he played the violin in the orchestra of the Royal Amateur Orchestral Society and also had the honour of a seat on the Council. At St. Thomas's Hospital for 10 years or more no function was complete without one of his violin solos Dr. Toller was possessed of a very remarkable personal charm, the outcome of his affectionate, impulsive nature. Everything he did was done with an enthusiasm which seemed the keynote of his character. He was perhaps inclined to be oversensitive and at times took offence where no offence was meant, but the artistic temperament will exact its toll and none of Dr. Toller's friends loved him the less for these little ebullitions. He had contributed little to medical literature, but the exactions of hospital appointments rendered this impossible, and his untimely death has robbed the future of its fruit. The wonder is, not that he did so little, but that in his short span of life he achieved so much. Few professional careers can have started with greater promise than his and it is an additional pang to his friends to feel that for long before the final blow his energies were so hampered by ill-health as to make it impossible for him to justify fully the hopes raised by his youth.

## THOMAS SMALLHORN, M.R.C.S. ENG., L.R.C.P., L.M. EDIN.

THE inhabitants of Eynsham, Oxford, have sustained a great loss by the death of Mr. Smallhorn who practised for 37 years at that place. Mr. Smallhorn was medical officer of health and public vaccinator for the Eynsham district of the Witney Union and was certifying surgeon under the Factories and Workshops Act. As a practitioner of medicine he was held in great esteem by members of his own profession and was much respected by his patients of all classes. The poor especially will not soon forget his many acts of kindness and benevolence. Mr. Smallhorn, who was in his sixty-fifth year, had never fully recovered from the after-effects of an attack of influenza of which he was a victim two years ago, and he died after a fortnight's illness on Feb. 9th. A widow, one son, and three daughters mourn their loss.

# Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In February the following candidates passed in the subjects indicated :—

*Surgery*—W. V. Braddon (Section I.), Cambridge and Manchester; T. S. Davies, St. George's Hospital; E. N. de V. Dawson (Section II.), St. Thomas's Hospital; J. C. S. Dunn, St. Bartholomew's Hospital; R Gauld (Section II.), London Hospital; S. F. Hickman (Sections I and II.), Royal Free Hospital; H. Jacques (Sections I. and II.), London Hospital; C. C. Morgan (Section II.), St. Bartholomew's Hospital; E. Osborne (Section I.), Birmingham; P. G. Sheppard (Sections I. and II.), Cambridge and Liverpool; and J. H. Williams, London Hospital.

*Medicine.*—J. E Bolton (Section II.), Leeds; R. Gillett (Sections I. and II.), Royal Free Hospital; C. E. A. Huddart (Sections I. and II.), London Hospital; M E. S. Scharlieb (Sections I. and II.), Royal Free Hospital; and C. Watson (Sections I. and II.), Dublin and Westminster Hospital.

*Forensic Medicine.*—D. Fletcher, St. Bartholomew's Hospital; M. E. S. Scharlieb, Royal Free Hospital; and C. Watson, Dublin and Westminster Hospital.

*Midwifery*—W. C. P. Bremner, University of Toronto; I. Griffith, London Hospital; M. E. S. Scharlieb, Royal Free Hospital; and R. H. Terry, Guy's Hospital.

The qualifying diploma of the Society in Medicine, Surgery, and Midwifery was granted to the following candidates:—J. E. Bolton, E N. de V. Dawson, D Fletcher, R. Gillett, C. E. A. Huddart, P. G. Sheppard, and C. Watson.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—FELLOWSHIP EXAMINATION.—The following candidates have passed the examination for the Fellowship :—

F. J. C. Heffernan, Miss M. R. Kapadia, H. Pringle, and M. J. Russell.

The following have passed the primary part of the examination :—

F. J. S. Heaney, Miss C. McCrea, and R. S. Ryce.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. Otto Lanz, Assistant to Professor Kocher of Berne, has been appointed Professor of Surgery.—*Brussels:* Dr. P. Van der Velde has been appointed Director of the Medical Clinic in the Hospital of St. Jean in succession to the late Dr. Destrée.—*Budapest:* Dr. Tiberius von Györy has been recognised as *privat-docent* of the History of Medicine. Dr. Ernst Emil Moravesik has been promoted to the Ordinary Professorship of Mental Diseases.—*Freiburg:* Dr. Hugo Sellheim, *privat-docent* of Midwifery and Gynæcology, has been promoted to an Extraordinary Professorship—*Greifswald:* Dr. Otto Busse, *privat-docent* of Pathological Anatomy, and Dr. Rudolf Rosemann, *privat-docent* of Physiology, have been promoted to Professorships.—*Leipsic:* Dr. Döllken has been recognised as *privat-docent* of Medicine.—*Lemberg:* Dr. Julius Marischler has been recognised as *privat-docent* of Internal Medicine, and Dr. Adam Szulislawski as *privat-docent* of Ophthalmology.—*Vienna:* Dr. Karl Biehl has been recognised as *privat-docent* of Otology.

prepared to accept that view on the understanding that there should be the inquiry which he had suggested.

The **PRESIDENT**: A resolution has been drafted on these lines

Dr. **McVAIL**: I was not aware of that.

The **PRESIDENT**: No; but Dr. MacAlister has a resolution in his hands. You will see it and see how far it meets your views.

Dr. **MACALISTER** said that certain resolutions which he had drafted he had intended to propose as an amendment to any motion for the adoption of the committee's recommendations. His idea was that they should, instead of taking the committee's recommendations, pass a general resolution in regard to the desirability of inspecting all the examinations of all the licensing bodies in chemistry, physics, and biology; but he now thought that they should concentrate any inquiry by them to and on schools The only new bit of information which they had before them was that in respect to institutions recognised by the Royal Colleges and not on the Council's list. For his part, he believed that even if the Colleges further investigated the matter they would find that the curriculum in all the schools they considered satisfactory was such as would satisfy neither them nor the Council. At any rate, the Council were entitled to ask the Royal Colleges to furnish full and particular information as to the curriculum of the various schools which they recognised. No doubt the inquiry would be a troublesome one to them, but after all that had had taken place he did not hesitate to ask the Colleges to take any trouble that might be involved. In asking them to do it the Council would be acting distinctly within their powers, and after they had obtained the information sought for they would be in a vastly superior position to determine as to whether they should come to a decision on the sufficiency or insufficiency of the first year's study in institutions on the Royal Colleges' list. He read the draft of the resolutions which he was prepared to submit.

Dr. **McVAIL** said that he would have no hesitation in seconding such resolutions

Some conversation ensued as to what should be done with the committee's recommendations, and eventually it was decided that they should not be proceeded with during the current session. The report containing them had, however, been put upon the minutes, and because of that the recommendations would remain "to a certain extent, alive," and capable of revival at any future time.

Dr. **PYE-SMITH** said that he and members round about him appreciated the skill with which the report of the Special Committee had been drawn up, and the moderate tone in which Dr. McVail had asked for its adoption by the Council. He ventured, however, to think that the attitude which had now been assumed towards this subject by Dr. McVail was a statesmanlike one which would not diminish his influence. He could not help sympathising with Mr. Horsley in the prospect of "no fight," and he thought that there should be a clear understanding on this—that the majority of the Council did not really wish to quarrel if a quarrel could be avoided

The following motions proposed by Dr. **MACALISTER** and seconded by Dr. **McVAIL** were then unanimously agreed to:—

I.

That the Council, under the powers granted by Section XVIII of the Medical Act, 1858, require the Conjoint Examining Board in England to furnish the Council with the following information regarding the course of study in chemistry, physics, and biology to be gone through by candidates for the qualifications L R.C P. London and M R C S. England—namely, in respect of each of the teaching institutions recognised by the Royal Colleges, but not approved by the Council.

(a) What are the methods of instruction, theoretical and practical, adopted in the subjects of chemistry, physics, and biology?

(b) What time is devoted by students to the recognised course of study in each of these subjects?

(c) What subjects, other than chemistry, physics, and biology, are students permitted to study simultaneously with these subjects?

(d) What were the ages at the commencement of the recognised courses in these subjects of the students on whose behalf certificates of study were accepted by the Examining Board in the year 1901?

(e) What are the names and qualifications of the teachers of chemistry, physics, and biology who give the recognised courses in these subjects.

II

That it is desirable that under the powers given by Section XVIII. of the Medical Act of 1858 the examination in chemistry, physics, and biology held by the several licensing bodies should from time to time be visited and reported upon

III

That in the first instance the examinations in chemistry, physics, and biology held by the Examining Board in England during the present year be visited by two persons appointed by the President on behalf of the Council, and that they be instructed to report on the scope, standard and sufficiency of these examinations.

It was also agreed, on the motion of Dr. **MACALISTER**, seconded by Dr. **BRUCE**, that—

The President and treasurers be requested to arrange for a suitable remuneration for the visitors, on the basis of the remuneration at present paid to the inspector of the examinations of the Apothecaries' Hall, Dublin.

Dr. **NORMAN MOORE** gave an undertaking that the Royal Colleges would furnish the utmost possible information to the Council in their inquiry.

Dr. **LITTLE** said that by the series of resolutions just adopted the Council had rather altered their bearing towards the English Royal Colleges, and he wished to ask Mr. Bryant and Dr. Norman Moore if they would endeavour to secure the authority of their respective Colleges to the cancellation of the intimation that the Royal Colleges would not require registration by the Medical Council in the Students' Register of candidates for their diplomas.

Dr. **NORMAN MOORE** could give no definite promise while the subject was still under discussion.

The **PRESIDENT** asked if the representatives of the two Royal Colleges would bring the matter before the authorities they respectively represented.

Mr. **BRYANT** and Dr. **NORMAN MOORE** replied in the affirmative.

### *The Executive Committee.*

On a vote by ballot Dr. Payne was elected a member of the Executive Committee in the room of Dr. Glover, who retired from membership of the Council at the close of last year.

### *The Midwives Bill.*

In answer to Mr. **BROWN**,

Sir **JOHN BATTY TUKE**, who had just arrived from the House of Commons, stated that the Midwives Bill had passed the second reading and had been referred to the Standing Committee on Law, which would probably take it into consideration within the next three weeks.

On the suggestion of the **PRESIDENT** it was resolved that the existing Committee on the Midwives Bill should be continued in order to watch proceedings on the Bill now before Parliament Sir John Williams and Mr. Brown were added to the committee, which is now composed of the President, Sir Christopher Nixon, Mr. Horsley, Dr. MacAlister, Sir John Williams, and Mr. Brown.

### *Vote of Thanks and Congratulations.*

Dr. **NORMAN MOORE** at the conclusion of business said: This is a special session and a most trying one, and we ought as a Council to pass a very hearty vote of thanks to the President for his extremely judicial and admirable conduct in the chair throughout it.

This proposal was received by the members with applause.

The **PRESIDENT**: I thank you, and let me say that the whole spirit and temper that has been displayed in this most important debate—one of the most important that has ever taken place in this Council and conducted in a thoroughly business-like way—has been most admirable, and I wish to congratulate the Council, because it is clear that we can do things in a thoroughly business-like way when we make up our minds to do so.

The Council then rose till the fourth Tuesday in May next.

## Obituary.

### LEVI COOPER LANE, LL D., M.R.C.S.,

OF SAN FRANCISCO.

WE regret to learn by telegram that Dr. Cooper Lane died on Feb. 18th at San Francisco, of which city he was a leading citizen. Born and educated in America, Dr. Lane visited this country in 1875 and became a Member of the Royal College of Surgeons of England in that year. A nephew of Cooper, the well-known surgeon of San Francisco, Dr. Lane joined him in his practice, to which he succeeded on Cooper's death Having wealth and no children he devoted himself to the foundation of the Cooper Medical College, in which he was professor of surgery, and later the Lane Hospital, both of which institutions he lived to see thronged with students, male and female

Mr. CORRIE GRANT asked whether it would be possible to make some provision for the loss of wages incurred by people who submitted to isolation.—Mr. LONG said that if the hon. Member meant provision out of the rates he did not think it would be possible. He did not think it would be at all desirable that district authorities, whether boards of guardians or municipal councils, should pay wages out of the rates. The detention need only be for a very short time. At present the local authorities could provide for the maintenance of people isolated but to go further and pay their wages would be a very serious step.—Mr. CORRIE GRANT pointed out that whilst maintenance had been undertaken by some local authorities, others had refused to undertake it under the impression that they had no power to assume such a liability.—Mr. LONG said he thought that in cases where local authorities had hesitated to act it had been from a misapprehension which he believed had now been removed

Mr. BARTLEY asked whether there was any power to prevent persons visiting small-pox patients.—Mr. LONG replied that the managers of the Metropolitan Asylums Board had absolute powers. He was informed that they only sanctioned visits to patients when it was believed that the patients were dying and it was found to be extremely difficult to refuse admission in such circumstances.

Mr. CORRIE GRANT asked the Secretary of State for War whether his attention had been called to a notice issued at the Brennan Torpedo Factory, Chatham, stating that employés would be required to notify to the office whether and within what dates they and their families had been vaccinated, and that it might be necessary to take steps to prevent the possibility of the disease being introduced into the factory through persons who had not taken the precaution of vaccination or revaccination. Would he explain under what authority revaccination was required; how recent a revaccination was required; and whether those who refused to notify to the office would be dismissed.—Mr. BRODRICK replied: The notice was issued in order to obtain information for guidance in the event of the epidemic becoming so serious in the neighbourhood of the factory as to require special consideration. It referred to the desirability of revaccination but does not enforce it. Non-compliance with the notice will not involve dismissal, but I must reserve complete freedom to the War Office to use any regulation which may be thought necessary to prevent small-pox being introduced into the factories.

### TUESDAY, FEB. 25TH.

### *The Legal Position of the Vaccination Officer.*

Sir JOHN ROLLESTON asked the President of the Local Government Board whether he had decided to apply to the Court of King's Bench for leave to intervene in the case of Moore *v.* Keyte in that court which raised the question of the control of boards of guardians over their servant the vaccination officer, and should leave be granted to instruct the law officers of the Crown to argue for the justices in support of the opinion of the Local Government Board; whether the assent of the Treasury was necessary and had been obtained for this expenditure; and whether, in order to secure the complete argument of the case in the interests of all boards of guardians, he was willing to recommend to the Treasury that pecuniary assistance for retaining the necessary counsel be afforded to the appellant Moore, a working man, or whether the Local Government Board would sanction the outlay necessary for that purpose by the board or boards of guardians interested in the question.—Mr. GRANT LAWSON, in the absence of Mr. Long, replied: The answer to the first point is in the affirmative and to the second in the negative. With regard to the last point I understand that the appellant in the case referred to is supported by the local anti-vaccination society. I could not undertake to adopt the course suggested by my hon. friend.

### *The Royal Army Medical Corps.*

Dr. E. C. THOMPSON asked the Secretary of State for India if he was aware that the Government of India refused to allow officers of the Royal Army Medical Corps the same pay and allowances as were granted to the officers of other branches of the army of the same rank; whether this refusal was delaying the issue of the new Royal Warrant for reform of the Royal Army Medical Department; and whether he would use his influence with the Indian Government to remedy the grievance which in the past had injured the interests of the Royal Army Medical Corps.—Lord GEORGE HAMILTON replied: No proposal has been refused by the Government of India, or made to them, to assimilate the pay and allowances of the Royal Army Medical Corps to those of any other branch of the army. The pay of officers of the corps serving in India was increased somewhat in 1897 and compares favourably with that of most other branches of the service. Various questions relating to the organisation of the corps are engaging the attention of the Government of India and I hope shortly to receive and consider their recommendations on the subject.

### WEDNESDAY, FEB. 26TH.

### *Midwives Bill: Second Reading Passed.*

The House devoted five hours of this sitting to a second reading debate on the Midwives Bill. Many of the speeches were extremely interesting, and next week we propose to publish a special report of the entire debate. In the meantime it may be said that Lord CECIL MANNERS moved the second reading of the Bill and Mr. TATTON EGERTON seconded the motion. Thereupon Sir JOHN BATTY TUKE moved as an amendment the rejection of the Bill, laying special emphasis on the omission of any provision for a penalty for women who practise without being certified. In the subsequent proceedings it came out very clearly that the sense of the House was favourable to the Bill in its main features. The HOME SECRETARY (Mr. Ritchie) spoke warmly in its support, while, of course, reserving the right to himself to scrutinise carefully its details on another occasion. Bowing to the sense of the House Sir JOHN BATTY TUKE did not claim a division on his amendment, and the second reading was carried without a division and the Bill was referred to the Grand Committee on Law. This reference to a standing committee obviates the stage of committee of the whole House. If the Bill comes back from the committee without amendment it proceeds to third reading, but if amendments are made then it has to pass through a report stage. As the Grand Committee on Law has little if any other work in hand, it will probably take up the consideration of the Bill on a comparatively early day.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BALDWIN, G. R., F.R.C.S. Eng., has been appointed Honorary Surgeon to Outpatients, St. Vincent's Hospital, Melbourne, Victoria.

BARRACLOUGH, A. M., M.B., B.S. Camb., has been appointed Certifying Surgeon under the Factory Acts for the Chapeltown District of the West Riding of York.

BEVERS, EDMUND C., M.A., M.B., B.Ch. Oxon., M.R.C.S., L.R.C.P., has been appointed House Physician to the Radcliffe Infirmary, Oxford.

CAREY, C. DE L., B.A., B.C. Cantab, has been appointed Second House Surgeon to the East Suffolk Hospital, Ipswich.

COLLINS, J. C., M.B., B.Ch., B.A.O. T.C.D., has been appointed Medical Superintendent of the Provincial Hospital, Auckland, New Zealand.

COLLUM, R. W., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Anæsthetist to the Charing Cross Hospital.

COOPER, EMOR R., M.B., Ch.B. Vict., has been appointed House Surgeon to the Devonshire Hospital, Buxton.

DAVENPORT, HAROLD DEVEREUX, L.R.C.S. Irel., has been appointed a Public Vaccinator for the District of Christchurch, New Zealand.

DOYLE, ANDREW ALOYSIUS, F.R.C.S. Irel., has been appointed Medical Officer at Roma, Queensland, and Visiting Surgeon to the Prison at that place.

EVERED, A. C., L.R.C.P. & S. Edin., has been appointed Quarantine Officer at Albany, West Australia.

HARVEY, WILLIAM, L.R.C.P. & S. Edin., has been appointed District Medical Officer for West Kimberley, Quarantine Officer for the Port of Derby, and Public Vaccinator for the Urban and Suburban Districts of Derby and Rural District of West Kimberley, West Australia.

JEFFERISS, FREDERICK B., M.R.C.S., L.R.C.P., has been appointed Assistant Physician to St. Bartholomew's Hospital, Rochester.

O'CONNOR, ARTHUR CHARLES, M.B., M.Ch. Syd., has been appointed Government Medical Officer and Vaccinator at Bulli and Coalcliff, New South Wales.

PARDEY, JAMES M., M.B., Ch.B. Melb., has been appointed Honorary Medical Officer to the Launceston General Hospital, Tasmania.

RAYNER, DAVID CHARLES, F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Lecturer on Practical Midwifery at University College, Bristol, vice Dr. W. C. Swayne, resigned.

SEABROOK, THOMAS E. FRASER, M.D. St. And., has been appointed Acting Medical Officer at Palmerston, Acting District Registrar of Births, Deaths, and Marriages for the District of Palmerston, Acting Health Officer at Port Darwin, and Acting Protector of Aborigines for the Northern Territory, South Australia, during the absence on leave of Dr. Frederick Goldsmith.

SHARP, ELLEN M., M.B. Lond., has been appointed Senior House Surgeon to the Victoria Children's Hospital, Hull.

SHORTT, W., L.R.C.P. and R.C.S. Edin., L.F.P.S. Glasg., has been appointed Coroner for the police district of Corowa, New South Wales.

SWAYNE, WALTER CARLESS, M.D. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Professor of Midwifery at University College, Bristol, vice Dr. Aust Lawrence, deceased.

TOD, HUNTER F., M.A., M.B., B.C. Cantab, F.R.C.S., has been appointed Surgeon to the Throat and Ear Department of the Paddington Green Children's Hospital.

VAN PRAAGH, HAROLD, M.D. Lond., has been appointed Casualty Physician at St. Mary's Hospital.

WHITE, E. A., M.D. R.U.I., has been appointed Medical Officer to the Isle of Thanet Joint Hospital Board.

WILLMOTT, ROBERT, F.R.C.S. Eng., M.R.C.S. Edin., has been appointed Official Visitor of the Hospital for the Insane, New Norfolk, Tasmania, for the year 1902.

ZIMPEL, ADOLPH, M.B., M.S. Aberd., has been appointed Junior Medical Officer, Department of Lunacy, New South Wales.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

BELGRAVE HOSPITAL FOR CHILDREN, 77 and 79, Gloucester-street, S.W.—House Surgeon for six months. Board and lodging provided and a gratuity of £5.

BIRKENHEAD BOROUGH HOSPITAL.—Junior Male House Surgeon. Salary £80 per annum, with board and washing.

BIRMINGHAM TAME AND REA DISTRICT DRAINAGE BOARD.—Bacteriologist. Salary £160 per annum.

BLACKBURN COUNTY BOROUGH.—Medical Officer of Health. Salary £550 per annum.

BRADFORD POOR-LAW UNION.—First Resident Assistant Medical Officer, unmarried. Salary £125, with rations, apartments, and washing.

BRIDGWATER INFIRMARY.—House Surgeon. Salary £80 a year, with board and residence.

BRIGHTON, HOVE, AND SUSSEX THROAT AND EAR HOSPITAL, Church-street, Brighton.—House Surgeon for six months, renewable. Salary at rate of £75 per annum.

BRISTOL GENERAL HOSPITAL.—Assistant House Physician. Salary £70 per annum, with board and residence. Also Assistant House Surgeon.

CENTRAL LONDON SICK ASYLUM DISTRICT.—Assistant Medical Officer. Asylum at Cleveland-street or Hendon as may be required. Salary £120 per annum, with board and residence.

**UNIVERSITY OF WALES**—It has been decided that the installation of the Prince of Wales as Chancellor of the University of Wales shall take place at Bangor on May 9th

**NOTIFICATION OF CHICKEN-POX.**—Chicken-pox is now a notifiable disease at Paignton (Devon) The Northam (Devon) District Council and the Bath City Council have decided to add chicken-pox to the list of notifiable diseases

**SUPPLY OF VACCINE LYMPH**—At the meeting of the Plymouth Board of Guardians held on Feb 19th the public vaccinator asked the board to supply him with some vaccine lymph for revaccination purposes Some of the guardians opposed the application, but it was eventually agreed to by a majority of four votes

**NEW HOSPITAL FOR MONMOUTH.**—Lord Llangattock presided on Feb 15th at a special meeting of the subscribers to the new hospital at Monmouth It is stated that the building will cost £5000, and the subscriptions received, including £2000 from the chairman, are still short of the required sum It was decided 'to commence the building of the institution immediately

**PRESENTATION.**—At the distribution of medallions and certificates in connexion with the Padstow (Cornwall) branch of the St John Ambulance Association held on Feb 15th, the members of the class presented Mr R. Palk Griffin, L R C P. Lond , M R C S Eng , L S A , with an easy chair with inscribed brass-plate, as a mark of appreciation of his services to them as honorary lecturer

**THE LATE DR T. PEARSE**—Dr. Thomas Pearse died at his residence in Queen Anne-terrace, Plymouth, on Feb 20th, after a short illness, fróm heart failure following bronchitis Dr Pearse was born at Launceston, Cornwall, in 1828, and graduated as M D in Edinburgh and M B in Aberdeen in 1849, taking the diploma of L R C S Edin in the same year Shortly afterwards he joined his father, the late Dr W Pearse, in Plymouth, During the outbreak of cholera at Plymouth in 1849 he had medical charge of the cases at Cawsand and at a later period he rendered valuable service during a small-pox epidemic Dr Pearse was the senior member of the Plymouth Medical Society. He was much esteemed in "the Three Towns," especially by the poor, to whom he was always kind and considerate The deceased leaves three sons, the eldest of whom is in the dental profession while the other two are in the medical profession

**THE ROYAL INSTITUTION**—Musical and talking electric arcs formed the subject of the Friday evening discourse delivered at the Royal Institution on Feb 21st by Mr W Duddell. He said that the vapour column of an electric arc varied in size with variations produced in the current which gave rise to the arc and was sensitive to very small and very frequent variations From this it resulted that when the current from an ordinary telephone transmitter was added to the current producing an arc the vapour column of the latter underwent rapid changes in size and created aerial waves which reproduced the sounds spoken into the transmitter The effects obtained when the light of an arc was thrown on a selenium cell were also shown Any direct-current arc passing between solid hard carbon points could be made to give out a musical note merely by connecting a self-inductive circuit containing a condenser as a shunt round the arc The self-inductive circuit was simply a coil of wire, and the condenser consisted of alternate sheets of paper and tinfoil For the production of a musical arc it was necessary that the resistance should be low, which was probably the reason why the discovery was not made some years ago The pitch of the note emitted was regulated by the frequency of the alternating current in the shunt circuit This frequency could be altered in several ways, the best of which was either (1) to increase or diminish the number of turns in the coil of wire, or (2) to vary the capacity of the condenser The lowest note which he had been able to produce in this way was D below middle C on the piano Mr Duddell showed a small keyboard connected with arcs giving two complete octaves, and his sister then played on it the melody of a verse of "Comin' thro' the Rye" The tone was nasal in character, like that of a musette and the music as played was interspersed with the loud crackling and sputtering of electric discharges.

# Parliamentary Intelligence.

## HOUSE OF COMMONS

### THURSDAY, FEB 20TH

### *War Medal for Nurses.*

Mr CLAUDE LOWTHER asked the Secretary of State for War whether women who were employed in the Army Nursing service in South Africa by military authorities and whose work had been commended by the principal medical officer on the spot, were allowed to receive the medal if they did not hold a three years' hospital certificate —Mr BRODRICK replied The South African War medal is given to all nurses and nursing sisters who served in South Africa from Oct 11th 1899 but the term nurses and nursing sisters" is held to apply only to those specially appointed as such, and to the staff of any local charitable institutions in South Africa duly recognised by the military authorities there and utilised by them for the reception and care of the sick and wounded

### *The Inquiry into Workhouse Nursing*

Mr KENDAL O BRIEN asked the President of the Local Government Board whether the committee appointed by the Local Government Board to inquire into the reasons of the difficulty in obtaining nurses for infirmaries or sick wards of workhouses under the control of the master and matron had commenced its inquiry, and if so what evidence did it intend to take, where was the inquiry being, or to be, held, and what opportunities would be given to medical officers, superintendent nurses and others interested to give evidence —Mr LONG, in reply, said The committee have commenced their inquiry and are sitting twice a week at the offices of the Local Government Board It rests with the committee to determine what evidence they will take, but arrangements have already been made for hearing the evidence of certain Poor law officers and guardians or representatives of various Poor law and nursing associations and of other persons interested It is open to any person desirous of being heard by the committee to communicate with the secretary on the subject Such person should state his qualifications and the nature of the evidence he would be prepared to give

### FRIDAY, FEB 21ST

### *Public Health Appointments in Ireland*

Dr L C THOMPSON asked the Chief Secretary to the Lord Lieutenant of Ireland if he would give effect to his promise, made last session of Parliament on behalf of the Irish Local Government Board, that when vacancies occurred amongst consulting sanitary officers superintendent officers of health would be appointed —Mr WYNDHAM said in reply The statement made by me last session was that the provision in the Board's Sanitary Order of May, 1900 with respect to the appointment of a medical superintendent officer of health had not been acted upon in any case and that the opportunity to act upon it would only arise as vacancies occur in the office of consulting sanitary officer The Board is prepared in all cases when such vacancies may arise to sanction the appointment of medical superintendent officers of health

### *The Small pox Epidemic*

Mr CORRIE GRANT asked the President of the Local Government Board whether he was aware that a resident of Rugby while ill with small pox in one of the hospital ships under the control of the Metropolitan Asylums Board was visited on Feb 1st by his mother and sister, that he died the next day, and that the mother had since been attacked with small pox at Rugby and was now in the small pox hospital at Rugby, and whether any, and, if so, what precautions were taken by the Metropolitan Asylums Board to prevent the spread of infection by visitors to patients —Mr LONG replied: I am aware of the facts referred to by the hon Member As regards the concluding part of the question, I am informed that the following are the chief precautions taken by direction of the managers of the Metropolitan Asylums District to minimise the risk of infection being spread by persons visiting patients at their small pox hospitals The visitors on their arrival are invited to partake of a light meal in order that they may be physically better able to resist infection they are then seen by a medical officer who inquires into their condition as to vaccination and if necessary, urges upon them the advisability of immediate revaccination Before entering the wards the visitors are dressed in overalls and caps and whilst in the wards they are on no account allowed to touch, or in any way to handle their relatives or the beds on which patients are lying After a brief stay in the wards (some minutes only) the visitors are taken to a dressing room where the overalls and caps are removed and they themselves undergo a thorough washing of the hands and face before leaving the hospital premises The fact of every visit is communicated by letter to the medical officer of health in whose district the visitor resides whether that visitor has been recently revaccinated or otherwise In the case referred to in the question the two visitors refused to be revaccinated at the time of their visit to the ships

Mr CORRIE GRANT asked whether in this session the Government would bring in a measure enabling the local authority to enforce isolation upon persons known to have been in contact with others suffering from small pox and to provide reasonable compensation to such persons —Mr LONG said: The answer to this question must be in the negative I may state however, that I propose to issue a circular in the course of a day or two as regards the isolation of persons brought into contact with small pox, based on the views held by the medical officers of the department another before the altar of the orchid, and it may be interesting to recall the fact that even before the days of Gerard the red lily of Constantinople, as this author calls *Lilium Chalcedonicum*, was grown in our gardens. Within the past 15 years the interest taken in these plants has enormously increased, and we believe that we are not far wrong in stating that from Bermuda alone some 2,000,000 bulbs are annually exported, while from Japan 5,000,000 is not an exaggerated estimate. All who admire the lily must be grateful to Mr. Henry for having discovered the lily which bears his name.

### A NEW VACCINATOR.

*To the Editors of* The Lancet.

Sirs,—Will you kindly favour me with sufficient of your valuable space to mention that about three years ago Messrs. Down Brothers made for me an aseptic vaccinator which, acting on the same principle as the Cooper Rose, can be easily and effectually sterilised by holding in the flame of a spirit lamp, and which appears to me to be the only satisfactory way of doing so? Mr. Palmer's invention still retains the disadvantage of an interior of a cylinder to keep clean, and this is not easily done. I am, Sirs, yours faithfully,

G. G. Gidley.

Cullompton, Devon, Feb. 24th, 1902.

### WANTED—AN ANNUITY OFFICE.

*To the Editors of* The Lancet.

Sirs,—My attention has been drawn to the letter appearing in The Lancet of Feb. 15th, p. 487, under the heading "Wanted—an Annuity Office," and in answer to your correspondent's inquiry I have pleasure in saying that several insurance companies—this association among the number—are prepared to give weight to medical evidence of health in quoting terms to persons desiring to purchase annuities.

I am, Sirs, yours faithfully,

Albert G. Scott,
General Manager of the English and Scottish
Law Life Assurance Association.

12, Waterloo-place, London, Feb. 17th, 1902.

### HIS MAJESTY'S ILLNESS IN 1871.

Under the title of "The Nation's Wave of Suspense in 1871," Messrs. Houlston and Sons have published, at the price of 6*d*., a chart showing the course of the critical illness of H.R.H. Albert Edward Prince of Wales at Sandringham in November and December, 1871. The graphic curve, illustrating the decline of the Royal patient's health through various stages to a condition when hope was almost abandoned and its gradual rise to a state of convalescence, is placed between two parallel columns of letter-press giving the bulletins issued by Sir William Jenner, Sir William Gull, Dr. Lowe, and the other physicians in attendance. The "memento," which is published on thick paper, gives some contemporary and connected events, and has scriptural texts in the borders and quaint corner-pieces.

### THE SAVING OF LIFE AND LIMB BY THE ADOPTION OF AUTOMATIC COUPLERS.

Statistics to hand from America afford a powerful reason why automatic couplers should be adopted on all the railways of the world. The saving of life thereby has been enormous. In 1898 it was reported by an American commission that "in 1897 there were 219 less men killed and 4994 less men injured in coupling and uncoupling cars than in 1893 (the year the Act was passed) the number of men killed being reduced by one half and the number injured by one half." During 1899–1900, when the Act was rigidly enforced, the report issued in June, 1901, showed the number of men killed in coupling accidents to be less by 35 per cent. than in the preceding year, and the number injured less by about 52 per cent., and these results were in spite of more powerful locomotives and heavier loads. Surely in the light of such eloquent facts as these it is nothing short of a scandal that life should be sacrificed any longer because many railways refuse to adopt automatic couplers.

### TRACTATUS DE LAPIDIBUS.

*To the Editors of* The Lancet.

Sirs,—There has lately come into my possession a fragment of an old Latin book on medicine. The fragment consists of chapters 25–140 and it is headed on each page "Tractatus de Lapidibus." So far as I can make out each chapter describes a certain stone with the aid of a primitive illustration and then follow several paragraphs headed "Operationes" describing the action and uses of the various stones. Any information which your readers can supply me with, as regards date of publication, author's name, or value; I should esteem a favour.

I am, Sirs, yours faithfully,

Oscar B. Trumper, M.B. Vict.,

Searle Lodge, Market Rasen, Feb. 23rd, 1902.

*Scalpel.*—The Pharmaceutical Society of Great Britain and the Society of Apothecaries of London hold examinations qualifying candidates to dispense medicines. Our correspondent must state the exact circumstances under which he requires to dispense medicines before his questions can be answered fully.

*Sufferer* can obtain full information from his medical attendant. He may also be relieved to hear that the complaint from which he suffers is probably of no consequence.

Communications not noticed in our present issue will receive attention in our next.

## Medical Diary for the ensuing Week.

*N B —A fee of 5s is charged for the insertion of Notices of Births, Marriages, and Deaths*

## Notes, Short Comments, and Answers to Correspondents.

### PUBLIC VACCINATORS AND GUARDIANS OF THE POOR

THE public vaccinators of the Holbeach Lincolnshire District are at present paid the following fees for vaccination and revaccination cases at the surgery *2s 6d* , cases within two miles of the surgery *5s* , and cases over two miles from the surgery *7s 6d* It will be noticed that *5s* and *2s 6d* are the minima allowed by the Local Government Board Like Mrs John Gilpin the guardians of the poor at Holbeach have a frugal mind at least as regards payments to other people and at a meeting held on Feb 20th the matter came up for discussion From the report of the meeting in the *Spalding Guardian* of Feb 22nd we learn that Mr Cragg expressed the opinion that ' it would not be very hard on the doctors if we brought it down to the minimum fee in all cases Mr Brothwell thereupon said ' I think the same myself A letter was read from Mr A. B Vise one of the public vaccinators in which he stated that during the three years 1899 1900 and 1901 he had been paid by the guardians for 20 successful vaccinations Of this number only 24 were distant under two miles from the town Of the others 121 were distant *between two and three miles,* 22 between *three and four miles* 21 between four and five miles 11 between five and six miles 12 between six and seven miles and four between seven and eight miles Besides these cases he had had to make 121 unpaid journeys in only 12 of which had he to go less than two miles The clerk asked Mr Brothwell if he would be prepared to undertake the work at the minimum fee Mr Brothwell however, did not give a definite answer but remarked that he had to do a good deal more work for a good deal less money We presume that Mr Brothwell is a medical man, although we cannot find his name in the Medical Register for 1901 or in the Medical Directory for 1902 under the section headed Provincial After some remarks from Mr R Merry, J P who charged the public vaccinators with arranging matters so that they got the higher fee Mr Cragg proposed and Mr Eastland seconded a motion that the existing contracts should be rescinded at 28 days notice and that in future no higher fee than 5s should be paid This was carried by a large majority, but finally the chairman ruled that a fortnight s notice of such a motion was necessary We refrain from comment until it shall be apparent what course the board of guardians is going to take

### THE R B ANDERSON FUND

DR ALFRED COX incloses a final list of contributions to the above fund and adds If there are any of your readers who even at the eleventh hour would like to do something to help to redeem the credit of the profession in this matter I would refer them to the treasurer of the fund the Manager Union Bank of London Chancery lane London, where subscriptions could be received up to Monday

### UNSEEMLY NOTICES

IN the *Peterhead Sentinel* of Feb 22nd appears a paragraph headed ' Dr Anderson s Successor It gives a variety of statements about the successor who we observe amongst other matters ' has travelled extensively in Egypt Turkey, and Russia We can scarcely imagine that the successor whose name for the present we withhold has sanctioned the insertion of this paragraph but he owes it to his profession to publish a disclaimer

### THE DISCOVERER OF *LILIUM HENRYI*

IN the March number of the *Girl's Own Paper* Eleonore d'Esterre Keeling writes a brief note accompanied with a vignette portrait of Mr Augustin Henry the discoverer of *Lilium Henryi* Though a Licentiate of the Royal College of Physicians of Edinburgh he is better known among botanists than he is among medical men He was at one time a medical officer in the Chinese Maritime Customs and he is still connected with that service though not in a medical capacity Even had Mr Henry not collected and sorted some 160 000 Chinese plants as the writer of the note states, he will always be famous as the discoverer of that handsome lily *Lilium Henryi*. By the way, is this ' the tallest lily that grows " as the note states? For instance is not *Lilium giganteum* taller? The genus lilium has always found admirers in spite of fashion which at one time kneels at the shrine of the tulip and at

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (3rd).**—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. F. G. Parsons: The Blood-vessels of Mammals in Relation to those of Man.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. R. Crocker: Clinique (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Saunders: Therapeutics.

ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.

**TUESDAY (4th).**—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. G. F. Still: Some Abnormal Psychical Conditions in Children. (Goulstonian Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. E. Squire: Clinique. (Medical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Dunn: Some Common Diseases of the Eye.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. Batten: Myopathies.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. W. N. Shaw: The Temperature of the Atmosphere, its Changes and their Causes

**WEDNESDAY (5th).**—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. F. G. Parsons: The Blood-vessels of Mammals in Relation to those of Man.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. H. Marsh: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Saunders: Therapeutics.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—8 P.M. Dr. Abercrombie: Ear Diseases without Discharge.

**THURSDAY (6th).**—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. G. F. Still: Some Abnormal Psychical Conditions in Children. (Goulstonian Lecture.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Davis: Medical Anatomy and Physical Diagnosis.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. F. E. Batten: Lesions of the Cerebellum.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Galloway: Dermatological Demonstration. (Post-Graduate Course.)

**FRIDAY (7th).**—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. F. G. Parsons: The Blood-vessels of Mammals in Relation to those of Man.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. Horne: Clinique. (Throat.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Ball: Diseases of the Tonsils.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. H. Becquerel: Radio-Active Bodies (in French).

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1901, which was completed with the issue of Dec. 28th, and the Title-page to the Volume, were given in THE LANCET of Jan 4th.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | | | TO THE COLONIES AND ABROAD. | | | |
|---|---|---|---|---|---|---|---|
| One Year ... ... ... | £1 | 12 | 6 | One Year ... ... ... | £1 | 14 | 8 |
| Six Months .. ... ... | 0 | 16 | 3 | Six Months ... ... ... | 0 | 17 | 4 |
| Three Months ... ... | 0 | 8 | 2 | Three Months ... ... | 0 | 8 | 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

## METEOROLOGICAL READINGS.

*(Taken daily at 8.30 a.m. by Steward's Instruments).*

**During the week marked copies of the following newspapers have been received:**—*Glasgow Evening News, Glasgow Herald, Southport Guardian, East London Observer, Bulawayo Journal, St. James's Gazette, Lancaster Post, Suffolk Chronicle, Standard, Manchester Courier, Newcastle Chronicle, Echo, Manchester Despatch, Yorkshire Post, Belfast News-letter, Nottingham Express, Cardiff Echo, Newcastle Leader, Darlington Echo, Hartlepool Mail, Star, Ipswich Times, Yorks Observer, Aberdeen Journal, Aberdeen Free Press (Weekly), Surrey Advertiser, Times of India, Morley Observer, City Press, South Wales Post, South Wales Daily News, Plymouth News, Westminster Gazette, Irish Times, Banbury Guardian, Freeman's Journal (Dublin), Essex County Chronicle, &c.*

the diminution of vascular supply to the mammary regions would certainly markedly arrest the development of mammary cancer. Accordingly I would never perform this operation myself unless the patients and friends distinctly understood its experimental nature and the absolute uncertainty which surrounded its results for good.

A certain number of my cases having had return of the disease after three years I can only adhere to a former statement, which I now publicly and strongly reiterate, that this time is far too short to allow of the term "cure" to be used in this disease. In one of my private cases the husband of the patient, a highly educated man, had read what I regard as the mistaken surgical opinions published on this point. His wife remained well for three years and he joyfully regarded her as "cured." When return took place his disappointment and disgust knew no bounds. I quote his exact words, they are of significance: "I would as soon my wife were under the veriest quack for the future as any member of your profession. Even in your profession published statements cannot be depended upon." I relate this to illustrate how dangerous it is to dogmatise concerning the results of a malady so protean and ill-understood as cancer, and how such methods weaken our position with regard to the educated portion of the public in a manner almost incalculable. I have repeatedly in my book and elsewhere dwelt upon the importance of every medical man understanding and realising the extraordinary differences which exist in pain, in rate of growth, and in virulency, in cancer of the breast in different individuals. It is want of knowledge which leads to belief in vaunted cures, the special drug which has been last taken receiving the credit through ignorance of the pathological changes in the disease. Let me briefly relate a remarkable case to illustrate the peculiarities which occur in the growth of cancer.

Over five years ago I operated upon a woman between 40 and 50 years of age for advanced hard carcinoma occupying a very bad part of the mamma, the sternal margin. As usual the growth had extended deeply into the intercostal space, and I followed it until the internal intercostal muscle had been removed and there seemed to be a serious risk of opening the thoracic cavity. I did not feel at all sure that I had extirpated the disease with that freedom which is so essential in operations for carcinoma. Rather to my surprise this patient remained well for close on five years, when pain and swelling occurred near the sternum and an obvious recurrence showed itself. For this condition I operated early in 1901. I found the sternum infiltrated with growth and was obliged to relinquish the operation. A livid tumour of the size of a large hazel-nut was present at the edge of the sternum. The patient did not see me again for nearly nine months and I wrote to inquire as to her case. She replied that she was so much better she had no cause to see me. On examination of her case I could hardly believe my eyes. The whole disease had disappeared and a deep depressed cicatrix alone remained, similar to that which obtains after removal of necrosed bone. This patient had not been taking violet leaves, cinnamon, or arsenic and quinine; neither had she had the benefit of the aerial therapeutics disseminated by Christian Science. Had one or other of these methods been in vogue what would have been said? If her ovaries had been removed what a triumph for oöphorectomy. What a lesson in humility should such a case teach us, how much we have to learn about the phenomena of cancerous disease.

These remarks would not be complete without reference to the efficacy or otherwise of the x rays upon cancer of the breast. I advised the treatment in one private case, but was not permitted to superintend the method or to watch the results. I can only speak from hearsay that the nodules withered away and great benefit was obtained. It is of the utmost importance that a series of these cases should be observed and that the true results should be published, and that not a few months after supposed "cure." A similar remark may apply to lupus and rodent ulcer treated by the same method. The results of scraping and applying caustic to rodent ulcer are often striking. The whole surface "heals over" and may remain well for months or for years, yet the disease too often returns locally. Can the "light treatment" show permanency of cure? These and many other such considerations point most strongly to the necessity for a laboratory where such questions can be studied, and for a research fund to reward impartial and disinterested observers for giving to the profession the true value of novel methods of treating these maladies.

During the six years ending in August, 1901, I have operated upon 59 cases of mammary carcinoma and one of mammary sarcoma. This list does not take into account many operations performed for recurrent disease, such as nodules in the skin of the chest and extirpation of diseased glands from the axilla. Some of these patients had been operated upon previously by myself and some by other surgeons. I have notes of 12 cases in this period of six years in which operation was refused. In nine of these extensive implication of the skin of the thorax and implication of the glands above the clavicle were the causes assigned for my refusal to operate. I may here mention that most of these were private patients and that the craze termed "Christian Science" was directly responsible for the hopeless and shocking state of a significant number of these deluded women. In one case signs of carcinoma of the spine were evident. In two cases large tumours of the liver coexisted, showing all the clinical symptoms of carcinoma. Two cases out of the 60 among the hospital class were lost sight of. I know that these patients were well two years after operation and they might be admitted into the "two years class" with justice. This leaves 58 cases for relation and discussion. Of the 58 cases particulars are tabulated of 40. The remaining 18 cases have been treated too recently to estimate their ultimate results. Some of them have been operated upon in the last six months, but among these 18 cases there have been two deaths. One was distinctly due to iodoform poisoning the other to bad sepsis. The latter case will receive due notice. In the 40 cases there was only one instance of slight suppuration about the centre of the wound, so that out of 60 cases all ran an aseptic course but two. The operations have been generally of the most extensive character, but healing has been both rapid and sound. In the 18 non-tabulated cases were two of speedy recurrence which will need special mention.

### METHOD OF OPERATING.

In all the 60 cases with the exception of two, where the diagnosis was deceptive and which receive special mention, the most thorough operation was practised. The axillary lymphatic tissues especially were carefully removed, and every scrap of fascia, both anteriorly and posteriorly. In cases where the axillary glands were infected, the lower part of the pectoral was removed and in several cases the pectoralis minor was cut across thoroughly to reach and to extirpate a chain of diseased glands extending towards the clavicle. The skin has always been very freely removed, so that in some cases I have been unable to bring it together after operation. I have paid great attention to such points as the warm clothing of the patient, the temperature of the rooms, and especially rapidity in operating. I believe the latter consideration to be of great importance, especially in elderly and bronchitic women. The anæsthetic has generally been gas and ether, followed by chloroform in the later stages of the operation. Drainage has been universally employed, sometimes in more than one part of the wound. It is curious how opinions differ upon the necessity of drainage in these cases. I am a strong advocate for the practice.

I will now mention particulars of two examples of rapid recurrence of disease which occurred in my 18 cases recently operated upon and not tabulated. In the first of these two cases the patient was an unmarried lady, aged about 40 years, of very dark and swarthy complexion, who had a swelling of the right breast which was painful, hot, and throbbing, and which had only been noticed for about two months. The affected organ "stood out" from the thorax and was of the size of a small turnip. It was red and hot and there was a distinct local feeling of elasticity or fluctuation. The temperature was raised at night and the resemblance to abscess was exact. Indeed, the diagnosis of suppuration had been arrived at. But the "peau d'orange" was marked and some enlarged glands were to be found in the axilla. The swelling was incised and was found to be a gelatinous hæmorrhagic growth, breaking down in the centre. Seeing the extensive implication of the skin the whole tumour and integument were removed by a circular incision, leaving a great gap on the thoracic wall of the size of a soup-plate. The pectoral was removed and the axilla was freely cleared. The huge wound was covered with flaps of skin "laid in" from the margin and sewn down with catgut. In about six weeks cicatrisation, extending from many centres, was complete. But about two months after operation very ominous signs showed themselves. These consisted in severe pains shooting down the back of the neck

# An Address

ON

# THE RESULTS OF OPERATION IN 60 CASES OF MALIGNANT DISEASE OF THE BREAST.

*Delivered before the Medical Society of Cardiff on March 6th, 1902,*

By A. MARMADUKE SHEILD, M.B. Cantab., F.R.C.S. Eng.,

SURGEON TO ST. GEORGE'S HOSPITAL; CONSULTING SURGEON TO THE HOSPITAL FOR WOMEN AND CHILDREN, WATERLOO BRIDGE-ROAD, AND TO THE HOSPITAL OF ST. JOHN AND ST. ELIZABETH, ETC.

Mr. President and Gentlemen,—The subject which I have the honour of bringing before the Medical Society of Cardiff to-night is one of surpassing interest to every medical man. I am especially glad of having the opportunity of speaking on the important matter of mammary cancer in this great town, the centre of a large population. I know that carcinoma of the breast is a prevalent disease in South Wales, and now that some hopes exist of the establishment of an institution where the phenomena of cancerous affections can be studied by experts the more facts we obtain from all parts of the country the better. Moreover, it is very true that some of the most curious and important clinical facts regarding cancer are found in the experience of elderly practitioners, who possess the confidence and secrets of private families, who have watched these cases to their terminations, and who have noticed the extraordinary vagaries and peculiarities which they exhibit.

Before proceeding to the hard-and-fast portion of my paper I would take a summary of the present position with regard to the subject of cancer of the breast and briefly advance my own opinions founded on a now tolerably large experience. You are aware that a controversy has for some time been going on as to who is to claim the credit for the method of extensive operating now in vogue. There can be no doubt that many of our former surgeons, and notably Mr. Moore of the Middlesex Hospital in 1867, advocated strongly very wide and free operating. His views were strongly supported in America by the elder Gross in 1880, and personally I am inclined to attribute to Moore the principal credit for originating very thorough operation in mammary cancer, and I have supported that statement in my book.[1] Sir Mitchell Banks of Liverpool, Mr. Heath, and many other senior London surgeons of the day followed the same practice. Yet it is curious to observe that there were some prominent London surgeons of that period who performed and actually publicly advocated the most imperfect operations, even advising that the axillary glands should be left untouched unless they were obviously infected. The comparative ease and safety with which the breast alone can be removed, leaving cancerous tissues in the axilla, became dangerously fascinating from its very simplicity of performance and speedy healing. Disciples of the imperfect operators became numerous all over the country and incomplete operations were prevalent not only in this country but in others. Under these circumstances the extreme and sweeping operation recently advocated by Halstead acted as a sort of "surgical revival," and, as has happened in religious matters, the backsliders from the true faith often embrace the new manifestations of truth with such astounding vigour that they excel their teachers, and certainly are apt to forget the similar doctrines promulgated by their own countrymen many years before. To Halstead, therefore, may be ascribed the credit of again forcing upon the attention of the profession the importance of very free operating, but I believe that this doctrine, like many others of the best methods of practice in surgery, originated in our own country and we are responsible to no one else for it. I may here express my own opinion that operations demanding division of the clavicle, dissecting out of glands in the neck, and removal of the upper limb and scapula can seldom come within the pale of legitimate surgery.

Regarding the parasitic origin of cancer of the mamma, as year after year passes I become more and more uncertain in what direction to inquire. Indeed, the matter is still an open one. Of one thing I am certain, that progress in this direction can only be made by proceeding with the utmost caution, collating all facts, clinical and otherwise, with truth and sincerity, and especially observing the results of experimental processes with the most rigid scepticism. Error is so easy, truth is so difficult, to ascertain. And in this, as in many of the difficult problems which beset the profession of medicine, some of the greatest obstacles to real progress are the hurry and inaccuracy of some of the most earnest workers.

In the last six years I have had numerous instances of the difficulties which hinder the early diagnosis of cancer of the breast, and these have been generally instances of small indurations and deep lumps, such as a patient finds quite accidentally. The lesson has been strongly borne home to me that the profession generally cannot be too much aware that the commencement of mammary cancer is insidious, quiet, and often quite painless Any slight "hardness" or "thickening" perceptible to the fingers laid flat on the mamma of a woman of the age of 40 years or upwards is a sign of the greatest import and demands immediate explanation. The diagnosis of a nodule of cancer from deeply seated cysts has time after time in my practice been shown to be impossible except by exploration Indeed, dubious tumours in the breast need exploratory operations as much as dubious tumours in the abdomen. It may seem heretical to state that the naked-eye appearances as exposed on exploratory incision are, in my own opinion, more likely to lead the surgeon right than are the results of microscopical examination. I have always found that when I have been in doubt between inflammatory tissue and early cancer the same doubt occurs to the microscopist if only he possesses the somewhat rare attributes of a sceptical mind associated with accuracy of observation. On the other hand, I have known serious prognostical difficulties to arise from relying too certainly upon dubious microscopical appearances. I canno recommend these observations too strongly to your serious consideration.

I feel sure that the general run of medical men do not fully appreciate the significance to be attached to infection of the axillary glands in mammary cancer. Only since I have been in the habit of removing the pectoral and clearing the axilla in every case has it dawned upon me that the glands are almost universally infected even in the early stages of mammary cancer. Time after time, when competent observers have made the written note "there are no enlarged glands" I have at the operation removed from under the pectoralis minor glands of the size of a hazel nut or almond, distinctly cancerous, which it was impossible to feel, even with the axilla opened, until the pectoralis major was removed. These glands usually adhere closely to the sheath of the axillary vein and the troublesome œdema of the arm so often seen as a sequel of operation for cancer of the breast is too often due to the fact that these important diseased structures have quite escaped observation at the primary operation. I have spoken at some length on this subject, for its vital significance can hardly be over-estimated, and I would conclude by stating my express belief that the being unable to feel enlarged glands in the axilla goes for little or nothing in the diagnosis of early cancer of the breast.

As regards the true value of the operation of removal of the ovaries for recurrent mammary cancer I fear I must say that I regard this proceeding as quite experimental. That a certain number of cases have been benefited I have no doubt; that a number have received no benefit whatever I am equally certain. My own personal experience is limited to two cases. They were both bad types of recurrent cancer in young vascular women. In neither of these did the slightest benefit occur. I also know of three private cases where the operation was performed by other surgeons and no benefit was obtained. I believe that the true reason why improvement—the withering of cancerous nodules, the relief from pain, and so on—has followed removal of the ovaries in certain cases is due to diminished vascularity of the mammary region sometimes caused by the operation. In certain cases of removal of the ovaries the breasts atrophy, hair grows on the lip, the patient generally emaciates, and the mental conditions of the woman become altered and curious. This change, it is well known, is by no means universal or even common, but, should it occur,

---

## TABLE SHOWING RESULTS OF OPERATION IN CASES OF MALIGNANT DISEASE OF THE BREAST.

| Case. | Years of age. | Married or single. | History and particulars of case. | Date and nature of operation. | Result. | Period of freedom from return. |
|---|---|---|---|---|---|---|
| 1 | 54 | Widow. | Noticed tumour in the left mamma for six months. Hard carcinoma. The patient spare and thin. Several axillary glands enlarged. | Sept. 15th, 1895. Mamma and pectoral removed. All fasciæ and glands as high as clavicle. | Was seen early in 1899, quite well. Present address not known. | 3 years. |
| 2 | 59 | Married. | A small tumour of the size of a chestnut at the upper border of the mamma. | Sept. 9th, 1895. Extensive operation. Pectoral fasciæ and glands removed, but not muscle. | In March, 1899 (three years and six months after operation), two small cancerous nodules were excised from the scar. In March, 1900, she was quite well. | 3 years and 6 months. |
| 3 | 53 | Married. | Extensive infiltrating carcinoma of the left mamma. Axillary glands implicated. | June, 1894. Extensive operation done. Pectorals and glands freely removed. | Quite well until June, 1898, when rapid ascites set in. The patient died in October. A partial necropsy revealed carcinoma of both ovaries and peritoneum. | 4 years. |
| 4 | 67 | — | Atrophic lump of carcinoma in the centre of the left mamma of three years' standing. | May, 1895. Whole mamma and fasciæ removed. Axilla thoroughly cleared. No deposits of cancer found in the glands by the microscope. | Died in 1899 from influenza and bronchitis. There was no return of disease. | 4 years. |
| 5 | 45 | Married. | Central carcinoma of 12 months' standing. Glands in axilla involved. | August, 1895. Extensive operation. Pectoral removed. Glands extirpated. | In September, 1896, a small nodule of carcinoma found in centre of axilla scar. This was again removed. Remained well until September, 1899, when the glands in the neck rapidly enlarged and she died with symptoms of cerebral tumours. No necropsy allowed. | 1 year. |
| 6 | 50 | Widow. | A small nodule of carcinoma at the lower part of the left mamma, of about the size of a hazel-nut. | March, 1896. Very free extirpation. Fasciæ and axillary glands removed, but not pectoral. Carcinoma found in the glands by the microscope. | Seen February, 1901, well. | Nearly 5 years. |
| 7 | 48 | Married. | Extensive carcinoma of the right mamma, the skin, and the glands, of at least nine months' duration. | June 20th, 1896. Extensive operation. Skin, glands, and pectorals removed. Skin-grafting employed. | Remained well for 10 months. Then signs of spinal mischief came on. The patient died paraplegic, with incontinence of urine and fæces, in two years. There was no local recurrence. | 10 months. |
| 8 | 58 | Single. | A large elastic tumour in the centre of the left mamma, noticed for 12 months. Once some bloody discharge escaped from the nipple. Much difference of opinion regarding the case. | August, 1896. A cyst found on exploratory incision which contained bloody fluid. On one part of its wall was a nodule of carcinoma of the size of a hazel-nut. The fasciæ and axillary glands were freely removed. | The patient has remained quite well. | 5 years. |
| 9 | 47 | Married. | A red itching patch round the site of a scar close to the right nipple for at least four years. When the patient was seen the disease had spread until the whole skin over the mamma was red, glazed, and shining. | September, 1897. The whole patch excised and the axilla cleared. Pectorals removed. The wound measured 14 inches by 12 inches. Extensive skin-grafting employed. | In January, 1899, extensive disease appeared in the cervical glands. There was no local return. | 1 year and 3 months. |
| 10 | 51 | Single. | Hard but extensive carcinoma of the centre of the right mamma under the nipple which was deeply retracted. A history of 12 months' duration. | "Complete operation," October, 1896. Pectoral removed and the infected axillary glands. | Remained well and able to work as a servant. In June, 1901, nearly five years after operation, the patient came with a small hard gland in the neck on the right side. This proved to be carcinomatous. There was no local recurrence, the scar and the axilla being quite healthy. | Nearly 5 years. |
| 11 | 52 | Married. | An elastic swelling in the centre of the left mamma of the size of an egg. It had been punctured twice and fluid had been drawn off. A history of about eight months' duration. | January, 1898. Exploratory incision revealed a curious tumour with cysts and solid growth. I opined it to be a cystic sarcoma, but microscopically it was a typical "duct-cancer." One of the axillary glands contained a nodule of growth of columnar epithelium. | Seen in 1901, quite well. | 3 years. |
| 12 | 60 | Single. | Extensive infiltrating carcinoma of the right mamma. The skin and axillary glands involved. Probable history extending over two years. Woman of great stature and physique. | February, 1897. The whole mamma with the skin removed. Pectorals also and axillary glands. An enormous wound left. Healed by skin-grafting. Convalescence retarded by mania. | Remained well for over a year. There was no local return. One year and three months after operation signs of cancer of spine were evident, from which she sank. | 1 year. |
| 13 | 63 | Widow. | A hard carcinoma of the size of an orange in the right mamma. Skin dimpled, nipple retracted. History of duration dubious. | June, 1897. Very free removal. The whole pectoral removed, and pectoralis minor divided. Many infected glands taken away. | On January, 1901, the patient wrote to say that she remained perfectly well. | Nearly 4 years. |

and round the occiput. The pains became agonising, so as to demand morphia, and soon a swelling was detected behind the pharynx which pushed forward the palate and was obviously a spinal growth. One morning this poor patient was found dead, and her medical attendant who has given me these details had little doubt from the condition of the neck that dislocation had taken place in the upper spinal vertebra, the ligaments being destroyed by the growth. But this, in the absence of post-mortem examination, must remain unconfirmed. The growth was ordinary soft carcinoma of a luxuriant type, the cells being abundant and very large This case was a typical example of inflamed infiltrating acute carcinoma. Such have been mistaken for abscess on different occasions with disastrous results. We see the best, or worst, examples of this formidable malady in young and especially pregnant women. So bad are the results of operations on these patients that I doubt if it is of much use operating upon them at all. I especially draw attention to this case for another reason. Any surgeon meeting with, operating upon, and publishing results of, this kind of mammary carcinoma will inevitably damage his statistical statements, if these be complete and accurate, as to freedom of his patients from return of disease. And the reverse is true that if the cases be selected and unfavourable ones of this kind be rejected the corresponding results will appear the more excellent.

The second case is an example of what sometimes occurs —namely, that an operation is done when, unhappily, dissemination has already occurred.

On Nov. 12th, 1900, I saw a strong, florid looking, married lady, aged about 45 years. In the axillary margin of the right mamma was an evident carcinoma with all the clinical signs of the disease well marked. The duration was quite uncertain. At the operation on Nov. 28th a soft mass of carcinoma was found and a very extensive operation was done The pectoral was removed as well as much diseased axillary lymphoid tissue Previously to the operation she had complained of "pains in the back" and rheumatic pains in the limbs, and a suspicion was aroused that all was not well. By the spring of 1901 these suspicions were confirmed She was beginning to lose control over the functions of the bowel and numerous areas of pain and numbness were evident over the lower extremities. She walked with difficulty and had constant pain in the back. She had emaciated greatly and bore the appearances of one dying from an incurable malady. There was no local recurrence, the scar and axilla being quite healthy. I have thought it right to relate this case shortly because I have seen others like it, and no operation, however extensive, can prevent the occurrence of such conditions. Are such cases to be termed "recurrence"? Are they not rather instances of multiple manifestations of disease?

I always make a practice of examining the visceral condition of a patient prior to an operation for mammary cancer and in this way the tumours of the liver before alluded to were discovered. But early carcinoma of the spine is so vague and difficult a disease to diagnose in its early stages that errors are very excusable and difficult to avoid.

I have said that one of the cases where suppuration occurred is only mentioned for completeness. The mischief was slight, limited to one part of the wound, and it speedily subsided. I have only referred to it to make the relation of my cases absolutely accurate. The other, however, which occurred among the 18 recent cases, was of a most disastrous nature, and shows us that even with all modern precautions absolute and certain safety is not obtainable.

The case I now refer to was that of a lady, aged about 50 years, who had a large mammary carcinoma. The operation was very extensive She had no renal mischief but had a feeble heart and a slight mitral bruit. The operation was performed with perhaps more than usually elaborate precautions I did not see the case afterwards, but it was left in the hands of a gentleman whose office was especially to manage the after-treatment of operations and who may therefore, with justice be looked upon as especially skilful in this department. All went well for three days when a blaze of sepsis occurred, and after lingering for about three weeks the patient died. The wound opened and became "dry" in appearance and it was obvious that some very potent factor of mischief had somehow been introduced Streptococci were found, and the case was treated with anti-streptococcic serum, but with only temporary benefit. Indeed, I have not seen so bad a case of sepsis for many years and it is the only one of the kind that has ever occurred to me in either private or hospital practice. I felt much ashamed of the case and should have been glad not to have been under the necessity of mentioning it, but its importance is undeniable, as showing the possibility of disaster when all precautions are used.

In 38 out of the 40 tabulated cases the operations have been of the most extensive nature, particularly as regards the removal of skin and fascia and axillary lymphatics. The sternal part of the pectoralis major has, in most instances, been removed. The pectoralis minor has been cut across and the fascia cleared from it. If the axillary glands are infected I feel sure that removal of the sternal part of the pectoral muscles is almost a necessity to remove high glandular infection. I have several times discovered by this means small cancerous nodules of the size of a pea lying close under the clavicle. I feel sure that these potent factors of future mischief would have remained undetected had the muscle not been removed. In this matter of removal of the pectoral I venture with all courtesy to differ from Sir Mitchell Banks who holds that the glands can generally be effectually extirpated by forcible retraction of the muscle.[2] I have generally been able to bring the skin together and this, where great tension exists, has been aided much by the making of lateral incisions and extensive dissecting up of the skin above and below. When much skin has had to be sacrificed and a large gap has been left I have filled this in by the process of implantation flaps rather than by Thiersch grafting, which I have found private patients particularly object to.[3] I have mentioned that drainage has been universally employed. In cases of very obese women, when an enormous chasm has been left, I always place a tube in the centre of the wound as well as posteriorly through the lower flap. An accumulation of fluid is very apt to form in such wounds towards the centre or sternal aspect This is a potent source of danger, for nothing is more apt to become infected by septic organisms that a collection of bloody serum, which is really an attractive and warm culture medium.

Next, as regards the result of these operations. One of the striking general features is the freedom from local recurrences; and, if local recurrences have taken place, they have been of a small or nodulous nature, again easily removed. Such phenomena as œdematous arm, agonising pain, and fungating masses of disease have been conspicuous by their absence I attribute this largely to the thoroughness with which the axilla has been cleared. That distressing sequel, gigantic œdematous arm, is generally due to infected glands implicating and pressing upon the axillary vein, which were not detected, or only partly removed, at the primary operation. When returns have taken place they have been generally again removeable, and very considerable periods of freedom from further trouble may be confidently expected.

Of the 40 cases, eight patients are found to be well for the highly satisfactory period of five years, going on to six years, four for four years and upwards, seven for three years and upwards, and 11 for two years and upwards The cases which showed local return within two years need special mention; they have been very strictly classified, and it is only right to point out that a second and slight operation has given to these patients a fresh period of freedom from return Prominent in this class is Case 2. Here after removal of a small nodule in the scar the patient remained well for over five years. In Case 5 the patient remained well for over three years after removal of a recurrence. In Case 17 the patient has every chance of prolonged good health. In Case 22 after removal of a small nodule the patient remained well for four years and died from a cause unconnected with cancer. In Case 30 the patient succumbed to cardiac disease nearly two years after removal of the nodule mentioned, and in the last case recorded the prospects of the patient are equally good. Thus, it may be said that out of the 40 cases over 30 received untold benefits from the development of modern operative surgery. What a contrast this affords to the long and extensive experience of the late Sir James Paget when he said: "Survivals of three years such as are now often termed 'cures' were not very rare, but I can remember very few who survived without recurrence more than five years."[4]

TABLE SHOWING RESULTS OF OPERATION IN CASES OF MALIGNANT DISEASE OF THE BREAST—(*Continued*).

| Case. | Years of age. | Married or single. | History and particulars of case. | Date and nature of operation. | Result. | Period of freedom from return. |
|---|---|---|---|---|---|---|
| 26 | 38 | Married. | For many months there had been a bloody discharge from the left nipple, and a swelling of the size of an almond existed there. The late Sir James Paget gave his opinion that this was a cyst and should be dissected out. | June 17th, 1896. Finding the mammary tissue round the cyst indurated I removed a liberal portion of it. There were several small cysts, and one contained blood, and there was a small growth on its wall. After a careful microscopical examination definite deposits of carcinoma were found in the indurated tissue. The evidences found were stopping of the ducts with large proliferating cells, and in some spots alveolar structures with large epithelial cells of a typical nature were found. | July, 1901. Remains perfectly well. Compare with Case 20. | 5 years. |
| 27 | 63 | Married. | A tumour in the lower part of the left mamma had been noticed for two years. Diagnosis was difficult. The tumour was principally submammary. | Oct. 9th, 1897. At the operation a carcinoma was found which had developed in a deep lobule of the mammary gland and had infiltrated the parietes below the pectoral muscle. There was much difficulty in removing it and free and wide excision could not be effected. The pectoral was removed and the axilla was cleared out. | In September, 1898, a recurrence took place in the scar. A tumour of the size of a cherry was removed, the thorax being nearly opened. The patient died in 1900 with signs of mediastinal tumours. | 1 year |
| 28 | 50 | Married. | Pain, swelling, and retraction of the nipple on the right side had been noticed for 12 months. There was a hard, fixed tumour at the inner aspect of the right mamma close to the sternum. | June 21st, 1897. Very free and sweeping operation. Pectoral removed and some diseased glands from the axilla. The growth was close to the sternum and here had infiltrated the internal intercostal muscle. | Remained well until May, 1901, then a nodule formed in the skin over the sternum. This was carcinomatous and the bone beneath was found to be infiltrated with cancer at its centre. | Nearly 4 years. |
| 29 | 50 | Married. | A tumour of the left mamma had been noticed for two years. A bad case, much infiltration of the skin and the axillary glands. | August 18th, 1897. Extensive operation. Both pectorals removed and the glands as high as the clavicle. | In September, 1898, this patient developed a large carcinoma of the liver from which she died. There was no local recurrence. | 1 year. |
| 30 | 50 | Married. | For two years a tumour of the left mamma had been noticed. A bad case of infiltrating carcinoma. Deeply depressed nipple and much infection of the skin. The glands extremely involved. Bronchitis and weak action of the heart were present. | Sept. 23rd, 1897. A very extensive operation. Pectorals removed and all axillary lymphatics. | Remained well till May, 1899. Then a small nodule of the size of a pea developed in the skin near the centre of the scar. This was removed under nitrous oxide. | 1 year and 8 months. |
| 31 | 50 | Married. | A tumour of the right breast noticed for two years. Occasional bloody discharge from the nipple. | July 27th, 1898. Exploratory incision revealed a carcinoma of the size of a small orange. There was a large hæmorrhagic cyst in the growth. Very free removal. The pectoral was taken away, and all axillary lymphoid tissue. | In July, 1900, this patient was well. She has now gone abroad. | 2 years. |
| 32 | 40 | Single. | An Italian surgeon discovered a small tumour in the left mamma and desired to tap it, assuring the patient that it was a cyst. She came to this country and many diverse opinions were expressed. I refused to diagnose the case and strongly urged exploration by incision. The tumour was a deeply-seated elastic swelling of the size of a walnut. | July 18th, 1898. Exploration discovered a soft growth distinctly encapsuled but hæmorrhagic and breaking down. The whole mamma and fasciæ with the axillary lymphatics were removed. The growth was a spindle-celled sarcoma. The microscopical characters were very clear and pronounced. | July, 1901. Is in good health, with no sign of return. | 3 years. |
| 33 | 64 | Married. | A tumour had been noticed in the right mamma for 18 months. Ulceration had occurred over the tumour for three months. A large mass of carcinoma. Discharge very offensive. | July 10th, 1898. Ulcer and skin adjacent destroyed freely with cautery. Then the whole mamma, the fasciæ, and the pectoral were removed, with the axillary lymphatics. | September, 1901. In good health. | 3 years. |
| 34 | 42 | Married. | In 1898 a tumour was removed from the left mamma. In six months another tumour formed and this also was removed, but it soon returned. On examination the left mamma was extremely cancerous, and it was only too obvious that the tumours removed were carcinomatous and that a proper free excision ought at first to have been performed. | May 3rd, 1899. I removed the disease by a very free operation. The intercostal spaces below the mamma were, however, infiltrated. | An inoperable return of disease in this situation occurred in six months. | 6 months. |
| 35 | 38 | Single. | A small tumour in the right mamma had been noticed for months. Diagnosis dubious. | Feb. 26th, 1899. Exploration revealed carcinoma. Free removal. | Remained well in September, 1901. | 2 years and 6 months. |
| 36 | 45 | Married. | For 12 months a small lump in the right mamma had been noticed. Unfortunately, opinions given were to the effect that it was nothing and could be left alone. A large carcinoma was found on examination. The symptoms were quite typical. | April 20th, 1899. The pectoral was removed and many diseased glands from the axilla. The carcinoma was of the colloid variety and infiltrated the entire breast. | Remained quite well in September, 1901. | 2 years and 6 months. |

TABLE SHOWING RESULTS OF OPERATION IN CASES OF MALIGNANT DISEASE OF THE BREAST—(*Continued*).

| Case | Years of age | Married or single | History and particulars of case. | Date and nature of operation | Result | Period of freedom from return |
|---|---|---|---|---|---|---|
| 14 | 37 | Married | A small cystic tumour at the base of the nipple on the left side Occasional bloody discharge A history of about 12 months *duration* Section showed a semi solid tumour of dubious nature | July, 1897 The whole mamma removed, with fasciæ and axillary glands Pectoral removed No deposits found in *the glands by the microscope* The tumour was a duct cancer | This patient remains well at the present time | Nearly 5 years |
| 15 | 57 | Widow | A large tumour with much infiltration of the skin and obvious gland implication on the right side Duration quite uncertain | Dec 4th 1897. Extensive operation, all skin over the mamma removed with pectorals and glands from the axilla Skin grafting had to be employed | June 16th, 1898 Recurrence in the skin all over the thorax and the abdomen Scores of small tumours of the size of peas or nuts were slowly forming The glands in the neck were implicated The patient was alive in August 1898 and was getting great relief from thyroid extract | 5 months |
| 16 | 63 | Single | In the right mamma an elastic tumour of the size of an orange Time of existence quite uncertain | Jan 17th, 1898 Exploration showed carcinoma with a large hæmorrhagic cyst A very extensive operation was done The pectoral was removed as well as the axillary contents | The patient remained quite well and was seen in August 1900 in good health Now address cannot be found | 1 year 8 months. |
| 17 | 36 | Married | A healthy young woman, the mother of two children whom she had nursed At the base of the left nipple was a small circular patch of dermatitis maligna Paget's disease Seen by several surgeons all of whom advised excision of the nipple and the areola The mamma and the glands seemed not to be affected | May, 1899 Acting upon my advice the whole mamma was freely removed with the integument and fasciæ The incisions ran at least four inches from the nipple, the breast being voluminous Dr Rolleston examined the mamma carefully and sections subjacent to the diseased skin appeared healthy I felt confident that the disease was cured and got rid of for ever | Remained quite well until the spring of 1901 when to my surprise she presented two nodules of the size of a pea in the scar These were freely excised and turned out to be spheroidal carcinoma The patient has since remained well | 2 years |
| 18 | 50 | Single | A small hard carcinoma in the left mamma, noticed for six months | March 1899 Free removal of the mamma skin, fasciæ pectoral, and all axillary glands No sign of carcinoma found there | June, 1901 Remains quite well | 2 years |
| 19 | 38 | Single | A carcinomatous tumour of the size of an orange below the nipple on the right side History suggestive of chronic mastitis previously | March, 1897 The whole mamma removed with axillary glands pectoral and fascia | The patient wrote in June 1901 to say that she was then married and in good health | Over 4 years |
| 20 | 38 | Married | A bloody discharge noticed from the left nipple for many months A swelling of the size of a large almond at the left side of the areola The late Sir James Paget saw the case several times and advised that only the cyst should be removed He was strongly against removal of the entire mamma | June 18th, 1896 An exploratory incision revealed a cyst with blood stained contents and abundant growth on its walls The breast tissue was indurated with several small cysts A wedge shaped portion was removed Under the microscope two pathologists found evidence of early carcinoma at one spot This was also hard and indurated to the naked eye Another consultation was held and it was discussed whether the whole breast should not be extirpated This *was declined* | This patient remains quite well I have no reason to doubt the diagnosis of early cancer. | Over 5 years |
| 21 | 60 | Married | Central carcinoma of the left mamma of two years' growth Small hard, and puckered A bloody discharge from the nipple | April 11th, 1896 The whole mamma the pectoral and the axillary glands removed | Remained well for three years Died from influenza No sign of recurrence | 3 years |
| 22 | 50 | Married | For two years retraction of the right nipple with hardness and stabbing pain had been noticed A large central hard carcinoma the skin being much involved | Sept 23rd, 1897 Very extensive operation Pectoral removed and all axillary lymphatics | Remained well until April, 1899, when a small nodule of the size of a cherry was removed from the scar In 1900 the patient was well In the spring of 1901 she died from "bronchitis" There was no local return according to medical testimony | Free for 18 months from real return. Free from serious trouble for 4 years |
| 23 | 76 (?) | Single | For three years the patient had had a tumour of left mamma Operation considered dangerous on account of bronchitis and feeble health The tumour now of large size fungating and bleeding but free of chest wall | July, 1899 Rapid and extensive operation The whole mass swept away, the pectoral retracted and the axillary glands dissected out A more complete operation not attempted on account of the feeble state of the patient | July, 1901 Remains well Marvellous improvement in general health No local return | 2 years |
| 24 | 42 | Widow | For one year a tumour was noticed on the right mamma. Typical hard central carcinoma | March 1896 Extensive operation Pectoral divided. | July, 1901 Well, has lately married again | Nearly 6 years |
| 25 | 44 | Twice married, no children | For nine months a tumour of the right mamma had been noticed The tumour was of the size of an orange and was moveable It felt very elastic as though it were a cyst or circumscribed abscess No nipple or skin symptoms | March 29th 1898 Incision revealed a soft growth which was encapsuled A very free operation was done but the pectoral was not divided There was some difference of opinion as to what the tumour actually was The majority of observers considered it to be a duct cancer | July, 1901 Remains quite well | 3 years and 4 months |

Case 17 illustrates very forcibly a truth which all candid surgeons have to admit, the impossibility of certain prognosis in cancerous disease. Here was a case of exceedingly slight infection of the skin round the nipple.[5] The whole mamma with a wide sweep of skin was freely removed as a precautionary measure only; competent microscopists stated that the breast substance was healthy, yet within two years nodules of carcinoma appeared in the scar. A case more favourably situated for permanent eradication could hardly be conceived, and falsification of diagnosis could hardly be more marked and disappointing. It is interesting to contrast this case with Cases 20 and 26. In each of these cases only a portion of the mamma was removed, and yet no recurrence has taken place over periods of five years. It is most important to observe that in both these cases cysts had formed, and the diagnosis was microscopical, not clinical; I am strongly of opinion that carcinoma associated with cysts is of a less malignant type as regards recurrence than others. Both of these cases are open to the criticism that the changes were inflammatory, not really cancerous. It is extraordinary that on examination of these cases the late Sir James Paget counselled only local removal of the cyst and surrounding tissues. He was against the idea that any cancerous change had occurred. It is right, therefore, to observe that in these most important instances cancerous changes were observed with the aid of the microscope rather in opposition to clinical opinion. But the tissues were examined independently by two of the best microscopists of the day who both were positive of cancerous change. At the same time I am coming more and more to the conclusion, which I fear many of my audience will term retrograde, to depend more and more upon naked-eye appearances and less upon microscopical, and unless a nodule of cancer be found showing the typical appearances on section to the naked eye to be hyper-cautious regarding any positive diagnosis made by the microscope only.

The after-results of cases of operation for mammary cancer would hardly be complete without reference to the movements of the arm and the utility of the limb on the affected side. I must say that the condition of some cases I saw a few years ago where very extensive operations had been done impressed me most unfavourably. The arm was practically tied down to the side by a neuralgic and painful scar, while the hand and forearm were useless and œdematous. I believe this condition is due to two factors—one the too free removal of axillary integument and the other the keeping of the arm bound to the side during the healing process. If the *axillary* integument be so diseased as to need free removal I doubt if the operation be worth doing. In my own cases I have merely retained the forearm in a sling for the first week. Then the nurse, by the insertion of cushions, gradually raises the arm to a right angle with the trunk. The cushions are removed and the arm depressed; they are again inserted and the arm raised. After a fortnight gentle passive movements of the limb can be substituted and gradually increased. I regard this after-treatment of the limb and the movements at the shoulder as being among the most important details in the after-treatment of operations where the axilla is extensively dissected out. I believe the methods I have sketched are less irksome and painful and more efficacious than any form of axillary apparatus or splint yet devised. I wish now to relate a very remarkable case which could hardly be tabulated, and yet has a direct bearing upon the story of mammary cancer.

In December, 1895, I saw a robust man of powerful frame, aged 68 years, who had a rounded, fixed hard tumour of the size of an orange on the thoracic aspect of the left axilla. The tumour had all the clinical characteristics of malignancy. The skin over it was livid and marked with venules. The history was curious. The patient stated that a "lump" had existed there for years which he used to examine and pull about, but only in the last six months had it alarmed him by its pain and increased size. He had been much exposed to the weather in the colonies and his skin was freckled and tanned with many pigmented spots and warts. He had also numerous papillomata scattered about on his skin One of these had been snipped off the hand, and I thought that the axillary tumours might be of the nature of secondary epithelioma in the glands. However, the tumour was removed. The operation proved to be very difficult, necessitating division of the pectorals. At the upper part there was a quantity of blood-clot, and free bleeding occurred on the removal of this. A strong evidence of malignancy now showed itself. The tumour had invaded the channel of the axillary vein, a piece of which vessel had to be removed between two ligatures. Speedy healing of the external wound occurred without mishap. The tumour was examined by two distinguished pathologists, and they both believed it to be spheroidal-celled carcinoma of a bad type. They also stated their belief that the growth had originated in a supernumerary mammary gland. This seemed very probable, and this is one of the reasons why I have referred to the case. The sequel is full of interest and of encouragement to surgeons. Feeling sure that I had scarcely removed the tumour with pathological certainty, I expected a return, and in two months this apparently took place. And here the importance of care was strikingly illustrated. Reflecting that much muscular tissue was excised the question arose whether the apparent recurrence might not be merely a mass of cicatricial tissue, and, indeed, on watching and waiting this turned out to be the case. For the mass, which formed slowly, reduced, and at the end of six months had quite melted away and disappeared. The patient was on the verge of taking the "Mattei" remedies, and imagine what he and his friends would have said had we rashly pronounced him to be suffering from recurrent cancer He is now in good health, able to shoot, with free use of the arm. It is upwards of six years since the operation. This is a termination which I could hardly have anticipated and only shows us the excellent results sometimes effected by operation for carcinoma, and how difficult the prognosis of such cases may prove.[7]

It is always customary to dwell upon our successful cases, but to make a paper of this sort useful and reliable our unsuccessful cases must also be alluded to and discussed. In Case 7 spinal growth probably existed before the operation. In Case 15 there was rapid local return in five months. This was entirely due to the skin infection at the time of operation—a most unfavourable condition and one difficult to combat. In Case 34 it was obvious that the preliminary removals before the patient came under my care were of the cancerous tumours only and that extensively infected tissues were left. Thus the intercostal spaces became infiltrated and complete extirpation was impossible. I have already related the two cases of rapid recurrences which have occurred in my 18 recent cases (not tabulated), but these make only five cases in the whole 60 in which the results of the operation may be said to be very poor and quite unsatisfactory, for the instances of local return where small nodules have been excised again and further freedom has been given can hardly be looked upon as altogether unfavourable. What is the explanation of Case 3? Here, after four years' interval of health, the patient died from carcinoma of the ovaries and peritoneum. There was no local return. Again, in Case 29 a large cancer of the liver is developed within one year, but no local trouble is noted. Many surgeons think that these are examples of independent cancerous growth and that it is quite possible for these to occur in elderly women with no breast cancer at all. It is noteworthy that I had to refuse to operate upon two cases because tumours of the liver coexisted. The correct pathological explanation of such cases is very dubious and is open to several interpretations, but their clinical importance is of obvious value and grave errors have arisen when the possibility of visceral tumours has not been fully appreciated.

In conclusion, the following lessons seem to be inculcated from the faithful record of these 60 cases:—1. That the risk of removing cancer of the mammæ by extensive operation is small and should not amount to more than 1 or 2 per cent. Sepsis is preventable, and when it occurs it is a blameworthy error on the part of the surgeon. 2. That early and free removal gives prospect of years of freedom and in a good percentage of cases of good health and enjoyment of life. 3 That the cases which do badly are (1) soft, rapidly growing cancer in young and vascular women, and (2) cases of long continuance before operation where the skin and cervical glands are widely infected 4. That in certain cases visceral cancers and cancers in the liver coexist with or rapidly follow operation, and the explanation of these is uncertain. 5. That the practice of early exploration by incision of small nodules

---

[5] This case was seen by the members of the Dermatological Society of London, and they all advised that only the area of affected skin with the nipple needed removal.

TABLE SHOWING RESULTS OF OPERATION IN CASES OF MALIGNANT DISEASE OF THE BREAST—(*Continued*).

| Case | Years of age | Married or single | History and particulars of case | Date and nature of operation | Result | Period of freedom from return |
|---|---|---|---|---|---|---|
| 37 | 50 | Married | A well-marked carcinoma of 13 months' duration in the upper quadrant of the left mamma. | Nov. 1st, 1899. Extensive operation. The pectoral and many diseased glands from the axilla were removed. There was suppuration at one part of the wound in this case and it was long in healing. | Remained well in September, 1901. | Nearly 2 years. |
| 38 | 50 | Single | Large carcinoma of the right mamma had been noticed for four months. | July 30th, 1899. Very free operation. A bad case. The pectoral and the diseased glands as high as the clavicle were removed. | Remained well in September, 1901. | 2 years. |
| 39 | 47 | Married | A tall handsome woman, the mother of a numerous family. Nine months' history of swelling in the right breast. All the signs of carcinoma well marked. | July 27th, 1899. Extensive operation. Bad case. Very widely spread glandular infection. Pectoral removed. | In September, 1901, the patient remained well. Had rheumatic pains in the bones which made me suspicious of the ultimate result. | 2 years. |
| 40 | 44 | Single | The left breast was painful and troublesome for nine months. It was indurated and coarsely lobulated, typical of chronic mastitis. The patient had lost two relatives from cancer and was very nervous. I advised removal of the mamma only, as a preventive measure. | June 23rd, 1899. Removed the mamma and the fasciæ. The axilla was not opened. On careful examination of the specimen by sections afterwards a small indurated area was found at one spot. This was pure carcinoma microscopically. I determined however not to interfere further but to await events. | In June, 1901, two small nodules appeared in the scars about its centre. They were well situated for removal. I advised free extirpation and also clearance of the axilla. The patient passed under the hands of another surgeon who operated, but I do not know in what manner. | 2 years. |

## REMARKS.

*Case 2.*—It is now getting on for five years and this patient is well. The return in the scar was quite insignificant.

*Case 4.*—This woman was very thin and spare, and I am not sure that the disease would have made much progress if left alone.

*Case 5.*—The recurrence was slight and the patient had a comfortable existence for about three years. This case illustrates the difficulty of permanent eradication when the axillary glands are extremely infected.

*Case 6.*—This was a very early case and the mammary substance seemed hardly at all involved.

*Case 7.*—This is an instance of a class of case where dissemination of disease has probably taken place prior to operation. The most extensive operating though preventing local return seems powerless to arrest systematic infection of this nature.

*Case 8.*—The microscopical characters of this case were those of duct cancer. They were very remarkable and difficult to interpret, but the cancerous nature of the growth was beyond doubt.

*Case 9.*—A most extraordinary example of dermatitis maligna. This disease was of the most extreme nature and lymphatic infection had doubtless occurred beyond the reach of operation.

*Case 10.*—This most interesting case can hardly be explained unless in the light of dormant infection in the cervical gland. The patient was peculiarly thin and spare and to this I attribute the long quiescence and feeble nature of the malady.

*Case 11.*—This patient will probably remain well. So far as I have seen these cancers exhibit a lesser grade of malignancy than do their fellows.

*Case 12.*—This was a case where no surgeon would have operated who was anxious as to his statistics of long freedom from return. Such operations are done only to alleviate local miseries such as pain and discharge. It is significant that there was no local return in this case.

*Case 15.*—This is a case of extensive infection of the lymphatics of the skin. Unless the operator is prepared to remove all the integument of the thorax he can hardly expect to get free of disease in such a case.

*Case 16.*—This is a most extraordinary case and one of great importance in the clinical history of Paget's disease. That such early and deep contamination occurred was not before present to my mind. This is one of those inexplicable cases which occur and teach us caution in dogmatism.

*Case 20.*—This is a remarkable and exceptional case in which the rules of surgery are distinctly violated and yet no return occurs. Such have been found before in the experience of surgeons, but such practice is fraught with dangers of speedy recurrence.

*Case 22.*—This case illustrates well how removal of a slight local return of disease is compatible with the absence of the malady for several subsequent years.

*Case 23.*—This is a very striking case on account of the age and feebleness of the patient.

*Case 25.*—This is one of those peculiar tumours which used to be termed sarcomata. The structure is very complex. It is an instance of encapsulation of certain malignant mammary growths.

*Case 26.*—This is a most important case as bearing on the value of the microscopical character of early cancer for clinical purposes. The examination was made by two experts. If they are correct the case is very difficult to explain.

*Case 27.*—This is a typical case of cancer growing in an unfortunate position and early infiltrating the thoracic parietes.

*Case 28.*—This was a most unfavourable case owing to the peripheral position of the cancer, and the long period of freedom is very remarkable.

*Case 29.*—This is one of those disputed cases in which it is dubious whether the growth on the liver is a cancer *de novo* or an infective growth from the long neglected mammary disease.

*Case 30.*—After being last seen the patient remained well for two years. She died in June, 1901, from cardiac failure and bronchitis. No local return.

*Case 31.*—I have every reason to believe that this patient is still well or she would have communicated with me.

*Case 32.*—This case illustrates forcibly the importance of exploratory incision before making an absolute diagnosis in deeply seated doubtful swelling.

*Case 33.*—The practice of destroying a cancerous ulcer with the cautery before operating is I think very important. Infection with the septic discharges of the freshly-cut surface is otherwise very likely to occur.

*Case 34.*—This was a case of mistaken treatment at the commencement.

*Case 39.*—This was an extremely bad instance of glandular infection. The freedom from return in this case has impressed me very much.

*Case 40.*—This case illustrates well the difficulty of distinguishing mastitis from early cancer. It is only after prolonged examination of such specimens after removal that early carcinoma can be detected, and even then errors are often made.

probably due to the shortening and pressing back of the face.

The greater importance of the internal maxillary in the lower mammals is interesting; in them it not only supplies the orbit and eye, but helps largely in the formation of the circle of Willis. This internal maxillary is the direct continuation of the external carotid and both jaws are built up round branches of it, the maxilla round the infra-orbital and superior dentals, and the mandible round the inferior dental. After noticing the varying development of the internal carotid and the formation of the circle of Willis I pointed out that the anterior communicating artery was not found in the lower mammals since the anterior cerebral was a single trunk for a long distance after leaving the circle.

After discussing the subclavian artery and its branches I ventured to construct what I regarded as a "generalised mammalian subclavian." In this the vertebral was the first branch, but the superior intercostal rose from the root of it, the thyroid axis and internal mammary came off opposite one another and had definite and constant relations to the phrenic nerve, while more externally still the posterior scapular was placed—a position which it often occupies in man. This arrangement of branches was not intended to apply to any one individual animal but to represent the average of all the specimens I have dissected.

The vertebral artery seems always to the present, but it does not necessarily join its fellow to form a basilar as in man; in the horse and dog, for instance, the basilar is formed by the occipital, while the vertebral expends itself in giving branches to the spinal canal, some of the blood from which reaches the circle of Willis by the anterior spinal artery. The thyroid axis was never once seen to give off an inferior thyroid branch, although this may occasionally rise from the lower part of the common carotid in monkeys. The branches from the so-called axis are therefore superficial cervical, ascending cervical, and sometime supra-scapular.

The branches of the axillary artery in man are more numerous and scattered than they are lower down in the scale, and when it is remembered how often branches which should be separate rise by a common trunk, one is not surprised to find that this fusion is the rule in other mammals. The division of the branches forms various combinations in different animals, but taking them altogether I am inclined to agree with Eichholz to a certain extent and to think that there is a tendency for the vessels to group themselves into two main branches, the first of which is ventral and the second dorsal. The ventral branch may be called the acromio-thoracic or thoracic axis and includes this artery of man as well as the superior, alar, and long thoracics; it has the inner head of the median nerve passing dorsal to it. The dorsal branch most often consists of the subscapular and dorsalis scapulæ, the two circumflexes, and the superior profunda. Unfortunately for exact attempts at dorsal and ventral delimitations, the subscapular artery very often comes from the ventral branch, while the anterior circumflex cannot be looked on as dorsal in distribution.

The brachial artery is chiefly interesting for its relations to the supra-condylar foramen. It is a mistake to think that when this is present the artery always passes through it, though it is true that it usually does so; the median nerve, however, always passes through the foramen, but the artery sometimes passes superficially. The high radial so often seen in man is represented in the Capuchin monkey and one kind of marmoset; in these, both New World forms, the radial rises from the thoracic axis of the axillary.

In the forearm we have in man traces of three different blood-paths to the hand; the oldest is the anterior interosseous, and in a dissection of a lizard it was shown that the blood passed from the flexor side of the elbow, between the radius and ulna, to the dorsal side of the wrist, and then, by perforating branches, passing between the metacarpal bones, to the palmar surface of the hand. That this vessel is really the anterior and not the posterior interosseous of man is evidenced by the fact that it keeps close to the interosseous membrane and does not lie between the two layers of extensor muscles. The arrangement in the lizard (a generalised reptile) also explains why man's anterior interosseous artery pierces the interosseous membrane. When the mammals are reached it is found more convenient to send the blood to the hand by an artery running down the middle of the flexor surface of the forearm accompanying the median nerve; this is the median artery, which occurs as an occasional abnormality in man and is always there in a vestigial condition as the comes nervi mediani. The ulnar artery is always present in mammals with well-developed fore-limbs, but until the Primates are reached it is only a muscular branch. In the Primates, however, beginning with the lemur, it takes over the work hitherto performed by the median and supplies the palm of the hand. The radial artery is formed by the fusion of two or more separate branches. In a generalised mammal, such as the squirrel, there are superior and inferior radials, the former rising from the brachial above the elbow and supplying the muscles of the radial side of the fore-arm; the latter, rising from the median in the lower third of the fore-arm and winding round the outer side of the wrist to the dorsum, becomes connected with the perforating and dorsal interosseous branches which used to be the continuation of the anterior interosseous when that artery was the main supply of the limb. The human radial is probably formed by the fusion of these two arteries, and the superficialis volæ is quite a late development, though in many of the primates it is a very important one. The passage of the radial between the first two metacarpal bones is merely an enlarged perforating branch, and in many mammals it is the second perforating, that between the second and third metacarpals, which is enlarged.

After discussing the thoracic and abdominal aortæ and their varying relations to the great veins I pointed out that in man the bifurcation of the aorta, if it does not occur at the lower margin of the fourth lumbar, is more likely to be lower than higher, and that this agrees with the mammalian tendency. In many monkeys the cœliac axis comes off as a common trunk with the anterior mesenteric, but this is a rare abnormality in man and is seldom met with in other mammals. The three branches of the axis are very constant throughout the mammalian class but extra hepatics are sometimes met with. In man the right kidney is more caudal in position than the left, though the arteries are usually opposite one another. In almost all other mammals the left is nearer the tail, and sometimes, as in the sheep and the phalanger, there is an enormous interval between them. This more caudal position of the left kidney and renal artery is sometimes reverted to in man in spite of the great development of the right side of the liver. Extra-renal arteries are sometimes found in man. These I only saw in two other mammals, the hedgehog and the guinea-pig, in which they appear to be normal, The spermatic or ovarian arteries always rise between the renals and the posterior mesenteric arteries. In many animals they come from the renals, in others from the aorta by a common trunk; both these are recognised human abnormalities. The posterior mesenteric is always absent in marsupials and may be wanting in members of other orders. The lumbar arteries are usually six in number, and in the Diana monkey, the lemur, and the grey seal one trunk serves for the origin of the two vessels of opposite sides. The middle sacral or caudal artery always rises above the bifurcation, as in man; after running down for some distance it gives off a branch on each side, and the three arteries run along the tail in the spaces inclosed by the chevron bones. In the Capuchin monkey, in which the tail is prehensile, extra branching occurs, so that there are seven arteries inclosed by the chevron bones; the most lateral of these supply the anterior segments of the tail, the median one reserving itself for the tip. This is an approach towards the rete mirabile found in the ornithorhynchus and some Edentates.

The aorta always divides into common iliacs in the Primates and Rodentia, and very often does so in the Chiroptera, the Insectivora, and the Edentata, and occasionally in other mammals. In other orders it is usual for the two internal iliacs to come off lower than the externals from a common stem which continues the abdominal aorta backward for a variable distance. It is probable that this last arrangement is the more primitive, since it is found in most reptiles There is a certain resemblance between the presence of common iliac arteries and the origin of the great trunks from the arch of the aorta. In those cases in which the trunks are fused—e.g., the carnivora and the ungulata—there is no common iliac, while in the Primates, in the Rodentia, and in many Edentata, in which the branches of the arch are separate, common iliacs are often found. The seal differs from most Carnivora in having an aortic arch like man's, and it is also remarkable for having common iliac arteries. The resemblance does not bear pushing too far, but it is striking enough to suggest that and indurations in the breast is of the first importance and should be strongly urged upon the profession generally, especially upon those in general practice who so often see these cases in their early beginnings and upon whom the great responsibility of prompt diagnosis falls 6 No one should undertake an operation for mammary cancer unless he is capable, and has had sufficient operative experience, to remove thoroughly all lymphoid tissues from the axilla, the leaving of infected glands towards the apices of the axillary spaces being a common source of failure in the results of this operation 7 The prognosis of mammary cancer is still dubious and sometimes instances arise which falsify ordinary experience Bad cases have long freedom from return Early cases show recurrence But such do not invalidate the rule, Operate early, operate extensively

ABSTRACT OF

# Three Lectures

ON

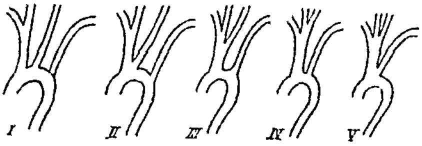
# THE BLOOD-VESSELS OF MAMMALS IN RELATION TO THOSE OF MAN.

*Delivered before the Royal College of Surgeons of England on March 3rd, 5th, and 7th, 1902,*

BY F G. PARSONS, F R C S ENG,
L R C P LOND,
LECTURER ON HUMAN AND COMPARATIVE ANATOMY AT ST THOMAS'S HOSPITAL, HUNTERIAN PROFESSOR AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND ETC

THE arch of the aorta in man, and in all mammals, is a left one, and the two chief points of interest about it are, firstly, its position and, secondly, the arrangement of its branches Its position is not always opposite the fourth thoracic vertebra, although this is, perhaps, the most usual place throughout the mammalian class, it is rarely a little nearer the head but more often nearer the tail.

In considering the arrangement of the great arteries I have records of over 260 dissections many of which were taken from different specimens of the same animal, and these show that there is a good deal of variation not only in the different orders but in different specimens of the same animal These different arrangements can only be satisfactorily classified by a series of diagrams covering the whole range of variations As an example of this the following classification of 107 records of members of the order of Primates may be instanced



| 1 | 2 | 3 | 4 | 5. |
|---|---|---|---|---|
| Man [illegible] | Man [illegible] | | | |
| Gorilla [illegible] | Gorilla, [illegible] | | | |
| Chimpanzee, $\frac{9}{12}$ | Chimpanzee $\frac{3}{12}$ | | | |
| Orang $\frac{3}{17}$ | Orang $\frac{14}{17}$ | Baboon [illegible] | | |
| | Gibbon [illegible] | Mangabey, $\frac{1}{2}$ | Mangabey [illegible] | |
| Macaque [illegible] | Macaque [illegible] | Macaque, [illegible] | | |
| Other cercopitheques, [illegible] | Other cercopitheques [illegible] | Other cercopitheques [illegible] | | |
| Capuchin, [illegible] | Spider monkey, [illegible] | | Spider monkey [illegible] | |
| Howling monkey, [illegible] | Howling monkey, [illegible] | | | |
| Squirrel monkey, [illegible] | | | | |
| Marmoset [illegible] | | | | |
| | Lemur, [illegible] | Lemur [illegible] | Lemur [illegible] | Lemur, [illegible] |

The foregoing material has been collected from the compilation by Keith and a paper by Patten, as well as from animals supplied by the Zoological Society. It will be noticed that the normal human arrangement is also normal for the gorilla and chimpanzee and for two varieties of South American monkeys, and this is especially interesting when it is remembered that in many ways these Platyrhini, or New World monkeys, more closely resemble man and the great apes than the monkeys of the Old World do The second figure shows a frequent abnormality in man (one in 10 according to the English Collective Investigation Committee) and is the normal in the orang, the gibbon, the macaque, and the spider monkey The third figure shows the normal of the lower monkeys of the Old World and of the lemurs, and only differs from the second in that the left carotid rises higher from the innominate stem The last two figures are only put in to include occasional variations in different members of the order The other orders of the mammalia were treated in the same way and I hope to have the opportunity of publishing the details later more fully than can be done here One or two points may, however, be noticed

In the Insectivora, Sirenia, Edentata, and Monotremata man's arrangement is the commonest, in the Rodentia the normal is man's commonest abnormality—that is to say, the left carotid rises from the base of the innominate In the Carnivora and Marsupialia there is a more complete fusion of trunks and the left carotid rises high up from the innominate as the normal, though there is a considerable range of variation In the Ungulata the fusion of trunks reaches its maximum, and one big branch, often called the anterior aorta, is the normal, though the pig, the hippopotamus, the elephant, and the hyrax have the left subclavian rising as a separate branch With regard to the elephant my material points to the conclusion that the ordinary figure of the text books is probably founded on an abnormality, this figure shows a symmetrical arrangement of trunks, the two carotids coming off from a common trunk in the middle and the two subclavians rising one on each side Out of nine records of dissections, two of which were kindly made for me by Professor Paterson, I could only find two with this arrangement In the other seven the left carotid rose from the root of the innominate, which was very short One more symmetrical arrangement is found in mammals, and that is the presence of two innominate trunks, this, I believe, is the normal for whales and bats, and is usually said to be so for Insectivora also though Dobson's writings and my own observation make me think that the human plan is commoner

With regard to the reasons for these various arrangements it is probable that the breadth, depth, and length of the thorax, the size and shape of the anterior thoracic outlet, and the distance of the arch of the aorta from the outlet all play a part In the whales and bats, for instance, the thorax is broad, shallow, and short, and in both double innominates are found, while in the ruminants the thorax is long and narrow and the trunks are all fused into a single vessel It is probable that in the whole mammalian class the arrangement of the great vessels most frequently met with is that in which the left carotid rises near the root of the innominate, so that this, which is the commonest abnormality in man, may be perhaps regarded as an atavistic variation in him The other common abnormalities of the human aortic arch, the origin of a vertebral from the aorta, and the dorsal position of the right subclavian are, I believe, very rare in the lower mammals, at least, I have met with no examples of them in over 260 records

I next described the carotid arteries and, among other things, pointed out that the superior thyroid is more often than not a branch of the common, instead of the external, carotid as in man; that the facial artery shows a series of transitions from a trunk confined to the submental region to one running up to the eye as in man. This fact suggested the possibility that the artery may have come up from the hyoid region with the muscles of expression In animals in which the head is bent, such as all the Primates and the squirrel, the external carotid is thrown into a constant S figure and the two convexities of the S give off respectively the lingual and posterior auricular arteries which are both very constant This curvature is less well marked in animals with stretched out heads and necks, such as the dog, and in man too the curve is not very evident but clearly not for the same reason; in him its disappearance is a constipated habit. Her weight in the summer of 1899 was 9 stones 2 pounds. The present ailment began in January, 1900, with a very intractable diarrhœa, accompanied with internal rumbling and purring noises, there being six or eight loose motions in each 24 hours. In the middle of February the patient took to her bed and was ordered an exclusively milk diet with lime-water. This treatment lessened the diarrhœa to three or four motions each day, sometimes attended with the passage of mucus. On March 8th she was seen in consultation with Dr. Harris of Manchester. 10 days later sand was discovered in the motions and found subsequently in all in which it was looked for.

On March 23rd, in Dr. Harris's absence, Dr. J. Dreschfeld's opinion was taken on the case. No ordinary methods of treatment had any effect in checking the diarrhœa and the formation of intestinal sand. The patient was sent up to London in April, and in Sir Dyce Duckworth's absence from town came under the care of Dr. A. E Garrod. At this time two or three motions were passed each day. They were loose, brown in colour, and on tilting the bed-pan the gritty sand could be seen at the bottom of the vessel, each motion containing about a teaspoonful of it. Early in May Sir Dyce Duckworth saw the patient with Dr. Garrod. She was pallid and sparsely nourished. The thoracic organs were healthy. On examining the abdomen it was found that the colon and its sigmoid flexure were, though empty, too readily palpable, and apparently thickened in their walls. The right kidney was moveable. There was a slight degree of pyrexia at this period, the temperature rising occasionally to 100° F. or a little above this. Specimens of the sand were obtained and submitted to examination. Full details of this are furnished in Dr. Garrod's report herewith. It will suffice to say here that it much resembled at first sight a deposit of uric acid, being of reddish-brown colour and finely gritty. It was insoluble in cold and boiling liquor potassæ and readily soluble in boiling nitric acid. Under a low power of the microscope particles of various shapes and sizes were seen, of a brilliant reddish-brown hue, and translucent.

The patient was confined to bed and kept on milk diet. For medicine salicylate of bismuth and bicarbonate of sodium were given in mixture. Under this treatment the diarrhœa was somewhat checked and the general health improved. The motions were rather more consistent, stained by the bismuth, but still contained sand. Towards the end of May the patient sat up for some time daily and went out for short walks, but there was now complaint for the first time of pain in the large bowel. Chicken broth, turtle soup, mutton broth, and koumiss were now given, and a mixture containing carbonate of bismuth, opium, and tincture of cinnamon. There were gradual improvement in most respects and less pain, but a good deal of rumbling noise in the bowels. The patient returned home early in June and continued the treatment under Dr. Surridge's care. Some benefit was gained by taking bael jelly and also from a mixture containing some aromatic sulphuric acid, tincture of cinnamon, and opium. In July, by our advice, she went to Plombières under the care of Dr. Bottentuit. She took baths and had rectal douches and drank the water in small quantities. All vegetable food was withheld, and digestion was found to be much more comfortable without it, as it caused immediate distension. She lost 10 pounds in weight while at Plombières. The next month was spent in Folkestone with some benefit and some weight was regained. On her return home she reported herself very much better. Her general health and her nervous tone had improved. There were still diarrhœa, with much flatulence at intervals, and some, though less, sand, accompanied with a great deal of mucus. Dr. Bottentuit prescribed bicarbonate of sodium in teaspoonful doses with advantage for the flatulent attacks. The appetite was better and more variety of food could be borne. During October there were alternations of constipation and diarrhœa, and a considerable quantity of sand was passed on Oct. 12th. She was next seen in November. She was rather pallid and languid, was easily tired on exertion, but had regained her usual weight, 9 stone 2 pounds. The large bowel no longer appeared thickened, as it did six months previously, but there was tenderness on pressure about the splenic flexure of it. There was still a looseness of the bowel, from two to four actions occurring daily, but no sand was passed. Her diet was altogether of animal food, and a little whisky was taken with one meal. The urine was turbid with lithates and deposited uric acid. The tongue was large, flabby, and thinly grooved. A mixture with liquid extracts of cinchona and bael and tincture of cinnamon was ordered, and milk with natural seltzer water was added to her diet. The catamenia were regular. She returned home about the middle of the month.

This case presented most of the characters that have been described in the few instances of the disorder that are already on record. It was, however, remarkable for the little pain which was experienced. In most examples of enteric lithiasis this appears to be a marked feature, occurring in paroxysms lasting several hours, somewhat akin to those associated with biliary and renal colic and attended with much flatulent distension and vomiting. According to M. Dieulafoy, who has recorded a series of these cases, there is commonly a family history of gout, and he regards the condition as one of the irregular manifestations of this disorder in many, but not in all, instances. In this case there was a distinct gouty history on the father's side. In a large proportion of the recorded cases there has been noted the co-existence of muco-colitis, often attended with the passage of mucous casts and sheds. Diarrhœa occurs in some cases, and constipation in others. The subjects of the disorder in two-thirds of the cases have been women, and the average age is about 35 years. Examples of it have been recorded in children under four years of age. Some of the cases described by continental observers, as will appear from Dr. Garrod's inquiries, are not truly cases of enteric lithiasis such as here described, the so called sand having been proved to consist of vegetable débris and not of inorganic matter.

*Characters and composition of the intestinal sand.*—When washed and dried in the air the gritty material passed with the motions had the appearance of a fine sand. Its ground colour was a deep brown with an admixture of pale or almost colourless particles. Under a low power of the microscope the individual granules were seen to have a great variety of shapes; some were roughly oval, some oblong or even rod-like, and others, again, were of very irregular outline Their colour varied from yellow to a warm brown. Some were translucent and others opaque, with the exception of their edges. Some had a finely granular appearance, but none of them showed any indication of crystalline structure Their longest measurement varied between 0·05 and 0·2 millimetres. When treated with an acid beneath a cover-glass the particles became surrounded by groups of bubbles and the solution of the inorganic constituents left exposed an organic basis, brown in colour, wholly structureless, and soluble in alkalies. No cellular elements could be seen and the organic basis certainly did not consist of vegetable débris of any kind. As in Eichhorst's case, the organic material, when washed with distilled water and stained with methylene blue, was seen to be rich in bacteria, both bacilli and micrococci being present in large numbers. When, on the other hand, the organic material was got rid of by combustion, the particles of inorganic substance left appeared like decolorised shadows of the original granules, which they resembled both in shape and size The air-dried sand lost considerably in weight at 100° C., owing to the expulsion of water from the organic basis, and the percentages of water and of organic and inorganic materials contained in it were found to be as follows:—

| | |
|---|---|
| Water | 12·40 |
| Organic material | 26·29 |
| Inorganic material | 61·31 |
| | 100·00 |

The inorganic residue left after combustion over a Bunsen's burner had a bluish-white tint and contained only a few dark particles. With the exception of such particles it was completely soluble in hydrochloric acid. This residue was submitted to analysis and was found to have the following composition:—

| | |
|---|---|
| Calcium oxide ($CaO$) | 54·98 |
| Phosphorus pentoxide ($P_2O_5$) | 42·35 |
| Carbon dioxide ($CO_2$) | 2·20 |
| Residue, containing traces of magnesium and iron | 0·47 |
| | 100·00 |

The presence of magnesium was beyond doubt, but the quantity was extremely small. Calcium phosphate was clearly the chief mineral constituent. The pigmentation of the sand proved to be somewhat complex and the small breadth of body must be the chief cause of separation of the branches of the aorta and of the presence of common iliac arteries.

The obturator artery is very often a branch of the internal circumflex in monkeys, and this usually comes from the internal iliac in these animals; lower down in the scale the obturator is often wanting, but in the monotremes it forms a rete. The internal pudic artery often rises from the sciatic trunk outside the pelvis; it is wanting in the hedgehog and the lemur, but in these specimens, both of which were females, the dorsalis clitoridis came from the vaginal and represented the occasional accessory pudic of man. It seems probable that the internal pudic was originally an extra-pelvic branch of the sciatic to the cloacal region.

The sciatic is the original main blood-path of the hind-limb. In the lizard the positions of the brachial and sciatic are quite similar, both of them running along the post-axial surface of the limb. In mammals, where the thighs become adducted and internally rotated the blood makes a new and shorter channel on the inner side of the thigh from the external iliac and deep epigastric which are present in the reptile. In man this main sciatic trunk is occasionally reverted to, but I have never seen it in any other mammal. Probably the position of man's thighs would render the reappearance of this artery easier than it would be in other mammals.

With regard to the branches of the external iliac, the deep epigastric is constant in position, and in the Capuchin monkey (two specimens) it gave off the obturator artery, so that this important human abnormality is probably atavistic. The deep-circumflex iliac, on the other hand, has in man shifted its origin from much higher up; in the Carnivora, for instance, it rises from the hinder part of the aorta.

The femoral artery forms a rete mirabile in the sloths and ornithorhynchus; its division into superficial and deep is not very satisfactory below the Primates. Among its branches the superficial epigastric is the artery of the inguinal and posterior abdominal mammary glands. The internal circumflex is nearer the pelvis and larger than in man; it often in Old World monkeys rises from the internal circumflex in the pelvis and supplies the same area as in man as well as the hamstrings; its origin is always higher than that of the external circumflex. The internal saphenous artery carries the blood to the foot in almost all mammals until man is reached and then it is only represented by the anastomotica magna. In its full development it accompanies the internal saphenous vein and nerve along the posterior margin of the tibia to about the middle, where it divides into two, one for the dorsum of the foot, the other for the sole. The dorsal branch behaves just as the dorsal artery of the hand does, dividing into dorsal, interosseous, and perforating branches, from the latter of which the deep plantar arch is formed in man. This dorsal branch clearly corresponds to the radial in the fore-limb, running as it does along the pre-axial border of the limb to the dorsum. The plantar branch divides into digital branches for the toes and lies between the long flexor tendons and the flexor brevis digitorum; its serial homologue in the forelimb is probably the superficialis volæ. Very often the dorsal branch of the saphena is absent and then the dorsum of the foot is supplied by the anterior tibial which is probably an older blood-path, as it is found in the lizard closely corresponding with the vascular arrangement of the anterior interosseous in the fore-arm. When the dorsal branch of the saphena is well developed it carries the blood to the dorsum and the anterior tibial becomes a mere muscular branch to the extensor muscles, its anterior tibial recurrent branch probably corresponding to the posterior interosseous and posterior interosseous recurrent of the forearm. In man the straightening of the knee has caused the blood to revert to its ancestral path to the dorsum through the anterior tibial. Another marked change which comes over the anterior tibial artery is its relation to the popliteus. In all mammals until the Primates are reached the artery invariably passes in front of the popliteus, but in the lemur the popliteal artery runs behind the muscle and the anterior tibial passes through the membrane beneath the lower border of it, and this arrangement continues until man is reached. The former, more generalised, mammalian arrangement is sometimes found as a human abnormality (twice in 106 cases in the report of the English Collective Investigation Committee).

The posterior tibial artery is a muscular branch running down between the two layers of flexor muscles and clearly corresponding with the median in the forearm. In man, when the saphenous artery disappears, the posterior tibial carries the blood to the sole.

The peroneal artery is not well marked until man is reached; its position on the post-axial side of the flexor surface of the leg suggests that it is possibly homologous with the ulnar in the forearm.

It is interesting to note that although the two limbs start with an identical arrangement of vessels in the lizard, they are modified in a different order in the mammalia; the fore-limb first adopts a median ventral vessel, the median, to carry the blood to the hand, while the hind-limb sends its blood through a pre-axial vessel—the saphenous. Later, in man, with the assumption of the erect position, the systems are reversed and in the leg the median ventral vessel (posterior tibial) carries the blood to the sole, while in the fore-arm this vessel is done away with and two lateral vessels, the radial and the ulnar, are used. At the same time in the leg the old anterior tibial blood-path of the lizard is reopened on the extensor side of the leg. These changes point to the ready adaptability of arteries to change of environment.

# A CONTRIBUTION TO THE STUDY OF INTESTINAL SAND,

## WITH NOTES ON A CASE IN WHICH IT WAS PASSED.[1]

BY SIR DYCE DUCKWORTH, M.D., LL.D. EDIN.,
F.R.C.P. LOND.,
PHYSICIAN AND SOMETIME LECTURER ON MEDICINE,
ST. BARTHOLOMEW'S HOSPITAL;

AND

ARCHIBALD E. GARROD, M.A., M.D. OXON.,
F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; MEDICAL REGISTRAR, ST. BARTHOLOMEW'S HOSPITAL

THE occurrence of intestinal sand has attracted the attention of observers for some years past. Cases presenting this symptom appear to have been of singular infrequency in the British Isles, for it is scarcely possible that they can have been often overlooked. English literature on the subject is, however, almost a blank, and the best text-books in this country and in the United States of America make but little reference to it. A good many cases have been noted and reported on the continent of Europe. The object of this communication is to attempt to place these examples of intestinal sand in their proper nosological position and to record a case of true, as distinguished from false, enteric lithiasis which came under our observation in this country. The particulars of it are as follows.

A married lady, aged 33 years, residing in the provinces, and leading a healthy life, began to suffer from diarrhœa early in 1900 and came under the care of Dr. E. Surridge. No cause for this ailment was made out. The previous health had always been fairly good. The last confinement had occurred three years before. The house which was occupied by this lady was built on a sandy soil and its drainage was reported to be in excellent condition and of recent arrangement. The water-supply was not good, being hard, and containing some organic impurities. The family history was as follows. Both parents were living. The father was a gouty man and a brother and sister of his were gouty. There were five sisters and two brothers; one of the latter suffered from colic. Bowel disorders were said to be prevalent in the family. The youngest sister of the patient, 20 years her junior, suffered badly at one time from a wide-spread eczema. When this disorder was subdued she suffered from asthma, the two conditions alternating. After local treatment and internal medication with arsenic she recovered her health. The patient had two daughters, aged respectively seven and three years, both of whom were in good health. After the last confinement the patient suffered occasionally from eczema around the anus for about 18 months. When this condition yielded to local and general treatment she became subject to looseness of the bowels, having previously been of

[1] A paper read before the Royal Medical and Chirurgical Society.

In some other cases the proportion of inorganic material has been considerably less. Thus Marquez found :—

| | |
|---|---|
| Organic matter, of animal origin ... ... ... ... ... ... | 72 |
| Inorganic, consisting of calcium phosphate and traces of carbonate ... ... ... ... ... ... ... ... ... ... ... | 28 |
| | 100 |

In a case recorded by Biaggi the sand was agglutinated into balls, from 6 to 8 centimetres in diameter, which readily disintegrated into sand. Much calcium phosphate was present, with traces of magnesium and sodium. The material passed in Mongour's case was *gravel* rather than *sand*, and it occupies an intermediate place between intestinal sand and the large intestinal calculi which are sometimes met with, and which are usually composed, in large part, of ammonium magnesium phosphate. Most of the particles were of about the size of an orange pip, but some attained to the dimensions of nuts. The analysis was as follows :—

| | |
|---|---|
| Organic material (by difference), water, iron ... ... ... | 29·28 |
| Magnesium phosphate ... ... ... ... ... ... ... ... | 26·82 |
| Calcium carbonate ... ... ... ... ... ... ... ... ... | 43·90 |
| | 100 00 |

*Seat of formation of "true" intestinal sand.*—The question remains to be considered how and where sand of this description is formed. Its composition excludes a biliary origin, for it contains no cholesterin, and bile pigment is only present in traces. On the other hand, there is much that points to its origin in the intestinal tract. Such sand is practically always met with in association with intestinal disorders and usually with muco-membranous colitis. The characters of the organic basis and the large numbers of bacteria which are included in it point to the intestine as the most likely seat of origin. When our patient was taking bismuth salicylates the sand passed had a uniform grey tint, but this may have been due to the deposition of a mere surface coating of bismuth sulphide. The richness of the material in urobilin and its poverty in unaltered bile-pigment affords a more satisfactory indication, and suggests that it is formed in a region in which the conversion of the bile-pigment into urobilin is already far advanced. There is good reason to believe that the principal seat of this change is in the upper regions of the colon. Concretions, chiefly composed of calcium phosphate and carbonate, can hardly be formed in any but alkaline surroundings ; but there is so much doubt as to the reaction of the contents of different parts of the intestinal tract, and especially under morbid conditions, that this does not afford any very clear indication of the exact locality in which the sand is formed. The nature of the inorganic constituents is fully compatible with an intestinal origin. Nor is it necessary to look to unabsorbed residues of the calcium of the food as the sole source of supply, for Voit, Friedrich Müller, and von Limberg have shown that a large part of the calcium excretion of the body is effected by the intestine, and Kobert and Koch found calcium, magnesium, and phosphoric acid in the material which accumulated in the empty and cleansed colon of a patient with a fæcal fistula. Like Dr. Thomson and Dr. Ferguson's patient, ours had taken milk and lime-water freely, and, as Bunge has shown, the amount of lime contained in milk is actually greater than that present in an equal volume of lime-water, so that the former may be regarded as a more important source of calcium supply than the latter.

The above considerations leave little room for doubt that true intestinal sand has its origin in the intestinal canal, for chemical and clinical evidence alike point in this direction. The nature of the contained pigments suggests the colon as the most likely seat of formation and the anatomical structure of the large bowel may be looked upon as more favourable than that of the small intestine to the sojourn required for the deposition of the earthy salts of which the material is so largely composed.

# SOME EXPERIMENTS TO DETERMINE THE ACTUAL EFFICACY OF IZAL OIL AS AN INTESTINAL DISINFECTANT.

BY M. H. GORDON, M.A., B.SC., M.B., B.CH. OXON.

BRILLIANT as are the results that have followed the employment of antiseptics in modern surgery, there is reason to believe that a limit to the scope of the antiseptic method both in preventing and in subduing disease has by no means yet been attained. The success of preventive medicine is witness to the utility of the same principle in another field. But the application of antiseptics in medicine proper—i.e., in curative as distinct from preventive medicine—is, owing to the lack of accurate practical knowledge no less than to the difficulties involved, at present comparatively restricted. Few subjects, however, are more worthy of careful study than the problem of the more skilful employment of antiseptics in medicine ; and this is my excuse for publishing the result of some experiments made with the object of determining the actual value of an intestinal antiseptic.

Izal oil, which is, unfortunately, a proprietary article, was discovered by Mr. J. H. Worrall while investigating by-products met with during the conversion of coal into coke. We are told that it consists chemically of oxidised hydrocarbons having a larger proportion of hydrogen to carbon than the members of the phenol $(C_6H_6O)$ series and a less proportion than the members of the methyl alcohol $(CH_4O)$ series. It has a high boiling point and is insoluble in water. The main preparations are (1) izal oil ; (2) an emulsion containing 40 per cent. of the oil and termed "medical izal" ; and (3) ordinary izal fluid which is also an emulsion containing 40 per cent of the izal oil, but not in this case, as in that of the medical izal, specially refined.

The extensive tests made by Dr. Klein[1] with regard to the germicidal properties of izal showed that while ordinary izal emulsion diluted to the extent of 1 in 200 is a disinfectant *in vitro* of no mean power, its toxicity was low, doses of 0·25 cubic centimetre of a 1 in 100 dilution administered to rabbits either by the mouth or subcutaneously producing no detrimental effect of any kind. The experiments of Professor Sheridan Delépine[2] supplemented those of Dr. Klein and confirmed the conclusion as to the value of izal as a disinfectant *in vitro*.

The history of the use of izal as a germicide *in vivo* is as follows. In consequence of Dr. Klein's results Mr. W. Bruce Clarke[3] thoroughly tested the efficiency of izal as a remainder of the material available did not permit of a complete and satisfactory investigation from this point of view. When some of the material was treated with acetic acid a scanty evolution of carbon dioxide was observed, and the gas rose to the surface in a stream of minute bubbles. The solution had the colour of brown sherry, and when filtered from the organic débris and shaken with ether it imparted to the ether a delicate pink tint, whereas the subjacent liquid remained of a rich yellow colour. The extraction was repeated several times, and the collected ethereal extracts were next shaken with a small quantity of distilled water, whereupon the pigment left the ether and imparted to the water a rich pink tint, which recalled that of a solution of acid hæmatoporphyrin. When examined with the spectroscope this solution showed a broad absorption-band in the neighbourhood of the D line, which lay between λ6120 and λ5370. With hydrochloric acid solutions of the pigment the band appeared composite, consisting of two darker bands united by a dark shading, and the position of the component parts was approximately as follows :—

| | |
|---|---|
| First dark band ... ... ... ... ... ... ... | λ5120—λ5890 |
| Dark shading. | |
| Second dark band ... ... ... ... ... ... ... ... | λ5760—λ5460 |

A second band in the neighbourhood of the F line (λ5060—λ4860) corresponded in position with that shown by a dilute acid solution of urobilin, and was apparently due to a scanty admixture of that pigment. When kept for a day or two, even in the dark, the pink solution became almost decolourised and the urobilin band alone remained visible. The pink pigment was also promptly decolourised by alkalies. *The very unstable pink colouring matter here present did not* agree in its properties with any pigment, fæcal or other, with which we are acquainted. The yellow liquid from which the pink pigment had been extracted with ether showed the band of acid urobilin with great intensity, and urobilin was apparently the chief colouring matter of the sand. It had all the ordinary properties of urobilin, as obtained from urine or fæces; was precipitated by saturation of a watery solution with ammonium sulphate; yielded a green fluorescence with zinc chloride and ammonia, and showed the characteristic E-band spectrum when partially precipitated *from a concentrated alkaline solution by the cautious* addition of an acid. The organic residue upon the filter-paper acquired a green tint on exposure to air, and when treated with a solution of sodium hydrate yielded a pale greenish-yellow solution, which did not become more distinctly green on standing but which gave Gmelin's reaction. Hence it was evident that among the colouring matters present was a small quantity of unaltered bile-pigment. Berlioz mentions the presence of urobilin in one of Dieulafoy's specimens, and Eichhorst observed the presence of biliverdin in some granules of the sand which he examined; but the only recorded case in which a special investigation of the contained pigments has been carried out is that of Dr. R. S. Thomson and Dr. A. R. Ferguson, who found, in addition to some urobilin, a pigment soluble in dilute hydrochloric acid and in alkalies but insoluble in water, alcohol, ether, and chloroform, and which was obviously not one of the recognised colouring matters of the bile.

We are greatly indebted to Dr. Thomson and Dr. Ferguson for the opportunity of examining a small quantity of the sand in question, which in appearance chiefly differs from ours in the larger size of the component granules. From a solution in acetic acid there was not extracted by shaking with ether any of the unstable pink pigment above described, and judging by the intensity of the absorption-band the amount of urobilin present appeared to be considerably less than in our specimens.

### VARIETIES OF INTESTINAL SAND.

Although the literature of intestinal sand is so scanty two distinct classes of materials have clearly been described by this name. These require to be clearly distinguished from each other and they may conveniently be described as *true* and *false* sand respectively

1. *False* intestinal sand is composed of remains of vegetable foods which have resisted the action of the digestive fluids and which may or may not have acquired some incrustation of earthy salts. One particular kind of vegetable débris is especially apt to appear as a sand-like material in the motions—namely, the sclerenchymatous particles which are so abundantly present in the flesh of pears, and especially in that of certain varieties. The occurrence of such sand in the motions was described by C. Robin in 1873, and some at least of the specimens described by Laboulbène in the same year were obviously of this nature. Eichhorst described a case in 1889, and Fürbringer called special attention to this material as simulating biliary concretions. Naunyn also refers to it as one of the varieties of so-called "biliary sand."[2] In this country specimens of this kind have been brought before the notice of the Pathological Society of London by Dr. S Delépine and Mr. S. G. Shattock. A specimen of pear sand in our possession, for which we are indebted to the kindness of Dr. J. H. Drysdale, is paler in colour and more coarsely granular (from 0·3 to 0·6 millimetres) than that passed by our patient and when burnt leaves only 1·76 per cent. of inorganic residue. Other observers have obtained from 2 to 3 per cent. of such residue—figures which contrast sharply with the much higher percentage of mineral constituents in specimens of true intestinal sand. The microscopic appearance of the *pear* sand is very characteristic. When examined under a low power the granules appear as if studded with projecting crystals, and after removal of any inorganic incrustation by an acid they are seen to be composed of woody cells, the thick, transparent walls of which are traversed by channels running from the narrow cell cavities towards the surface. In a word, the granules are easily recognised as identical with the particles of sclerenchymatous tissue in the fruit from which they are derived, and of which the patient will be found to have partaken freely. There is reason to believe that these woody particles may remain for some time in the intestine, and the expulsion of large accumulations of them may be preceded by severe colicky pain. The presence of a black sand-like material in the motions, consisting of cells derived from the banana, has also been described by some American authors. The dark colour is apparently acquired during the passage of the cells along the alimentary canal.

2. *True* intestinal sand, on the other hand, of which the material passed by our patient offers an example, has no such vegetable basis, and, wanting such a rigid skeleton, it owes its hardness and grittiness to the much larger proportion of inorganic material which it contains. The *organic basis of such sand is clearly of animal origin. Some* of the published analyses of such materials show a very close resemblance to that of our specimen. Thus Mathieu and Richand analysed the sand passed by their two patients with the following results :—

| | Case I. | Case II. |
|---|---|---|
| Organic material ... ... ... ... ... ... | 30·800 | 45·80 |
| Tricalcic phosphate ... ... ... ... ... | 64·206 | 46·68 |
| Calcic carbonate ... ... ... ... ... ... | 3·418 | 5·14 |
| Various mineral substances ... ... ... | 1·576 | 2·38 |
| | 100·000 | 100·00 |

Dr. Thomson and Dr. Ferguson's specimen had the following composition :—

| | |
|---|---|
| Organic matter ... ... ... ... ... ... ... ... ... ... | 28·5 |
| Inorganic matter ... ... ... ... ... ... ... ... ... ... | 71·5 |
| | 100·0 |
| In the organic residue: | |
| Calcic carbonate ... ... ... ... ... ... ... ... ... ... | 11·7 |
| Tricalcic phosphate ... ... ... ... ... ... ... ... ... | 87·3 |
| Insoluble residue (silica) ... ... ... ... ... ... ... ... | 1·0 |
| | 100·0 |

Berlioz analysed one of Dieulafoy's specimens and obtained the following figures :—

| | |
|---|---|
| Water ... ... ... ... ... ... ... ... ... ... ... | 11·25 |
| Nitrogenous organic material of fæcal origin ... ... ... | 22·24 |
| Fatty substances ... ... ... ... ... ... ... ... ... | Traces |
| Phosphoric acid ... ... ... ... ... ... ... ... ... ... | 17·56 |
| Lime ... ... ... ... ... ... ... ... ... ... ... | 26·22 |
| Magnesia ... ... ... ... ... ... ... ... ... | 14·05 |
| Silica ... ... ... ... ... ... ... ... ... | 8·68 |
| | 100·00 |

---
